**NORTH & SOUTH RAILROAD**  
**BRIDGE, TRESTLE AND CULVERT INSPECTION REPORT**

[illegible]

Way Departments shown on page 278, Vol. 27 of the Proceedings of this Association. To date reports on the following forms have been presented:

- Vol. 27 pp 277-278—Outline of typical reporting.
- Vol. 26 pp 843-855—Foreman's Daily Time Report.
- Vol. 27 pp 279-284—Labor Recapitulation and Distribution Sheet.
- Vol. 30 pp 646-650—Track Foreman's Daily Material Report.
- Vol. 31 pp 896-899—Foreman's Daily Report of Work Train Performance.
- Vol. 31 pp 896-899—Conductor's Daily Report of Work Train Performance.
- Vol. 34 pp 235-237—Foreman's Daily Report of Work Equipment.

This Committee this year submits a form to cover the Recapitulation and Distribution of Material.

Investigation by the Committee shows that some roads have forms with printed headings covering all items involved; others have forms partially printed, while others use forms with no printed headings.

The Committee believes that generally speaking a form with no printed headings is more flexible and economical. The form submitted by the Committee shows the **title headings on the sheet printed but leaves all other spaces blank to be filled in.**

In the exhibit as presented the form is partially filled out to show the manner in which it can be used.

## Appendix G

### (C-3) FORMS USED BY RAILWAY WATER SERVICE DEPARTMENTS, COLLABORATING WITH COMMITTEE XIII—WATER SERVICE AND SANITATION

D. C. Teal, Chairman, Sub-Committee; James Erskine, W. E. Gardner, F. C. Kane, J. R. Leguenec, Jr., F. X. Soete, James Stephenson and Louis Wolf.

Four forms dealing with water station records are shown in the 1929 Manual on pages 955 to 958, inclusive. Since the adoption of these forms in 1909, many changes have been made in the organization of Railway Water Service Departments and in the methods of pumping and treating water.

The work of the Committee has been to develop an up-to-date system of Water Supply Department forms to replace the obsolete ones now appearing in the Manual.

In the pursuance of the assignment, forms now in common use by Railway Water Service Departments have been collected and classified. Forms representing each general classification have been designed and presented to the Association during the past three years as follows:

| <i>Name of Form</i>                                            | <i>Proceedings Reference</i> |             |             |                    |
|----------------------------------------------------------------|------------------------------|-------------|-------------|--------------------|
|                                                                | <i>Vol.</i>                  | <i>Year</i> | <i>Page</i> | <i>Form Number</i> |
| Cost of water production.....                                  | 32                           | 1931        | 524         | 1302-Rev.          |
| Monthly report of water station operation.....                 | 33                           | 1932        | 599         | 1301-Rev.          |
| Quarter monthly report of water treating plant operation ..... | 34                           | 1933        | 240         | 1301-A             |
| Record of water station facilities.....                        | 34                           | 1933        | 241         | 1303-Rev.          |

Form 1302-Rev., 1301-Rev., and 1303-Rev., are up to date versions of forms now appearing in the Manual. Form 1301-A is a form necessitated by the development of present-day water treatment practices and has no counterpart at present in the Manual.

It is believed that the above forms together constitute an up-to-date system of essential water supply department forms that fulfill the requirements and cover the needs of present-day water service organizations.

### **Action Recommended**

In order to properly close the assignment, the Committee makes the following recommendations:

#### **Cost of Water Production**

It is recommended that Form 1302-Rev., together with text relative to same, as presented on pages 523 and 524 in Vol. 32 of the 1931 Proceedings, be published in the "Records and Accounts" section of the Manual. It is further recommended that the designation "Form 1302-Rev." be changed to read "Form 1130".

It is recommended that Form 1302 appearing on page 956 of the 1929 Manual be withdrawn.

#### **Monthly Report of Water Station Operation**

It is recommended that Form 1301-Rev. together with text relative to same, as presented on pages 599 and 600 in Vol. 33 of the 1932 Proceedings, be published in the "Records and Accounts" section of the Manual. It is further recommended that the designation "Form 1301-Rev." be changed to read "Form 1131".

It is recommended that Form 1301 appearing on page 955 of the 1929 Manual be withdrawn.

#### **Quarter Monthly Report of Water Treating Plant Operation**

It is recommended that Form 1301-A, together with text relative to same, as presented on pages 239 and 240 in Vol. 34 of the 1933 Proceedings, be published in the "Records and Accounts" section of the Manual. It is further recommended that the designation "Form 1301-A" be changed to read "Form 1132".

#### **Record of Water Station Facilities**

It is recommended that Form 1303-Rev., together with text relative to same, as presented on pages 241 and 242 in Vol. 34 of the 1933 Proceedings, be published in the "Records and Accounts" section of the Manual. It is further recommended that the designation "Form 1303-Rev." be changed to read "Form 1133".

It is recommended that Form 1303 appearing on page 957 of the 1929 Manual be withdrawn.

#### **General**

It is recommended that suitable reference notes to above forms be published in the "Water Service" section of the Manual.

## Appendix H

**(E-1) METHODS AND FORMS FOR GATHERING THE DATA FOR KEEPING UP TO DATE THE VALUATION AND OTHER RECORDS OF THE PROPERTY OF RAILWAYS WITH RESPECT TO:**

- (a) Changes made necessary by government regulations.
- (b) Simplicity and practicability of use.

P. R. Leete, Chairman, Sub-Committee; B. A. Bertenshaw, E. Y. Allen, E. V. Braden, V. H. Doyle, W. E. Gardner, A. T. Hopkins, W. W. James, W. R. Kettenring, C. A. Knowles, E. W. Metcalf, A. T. Powell, H. L. Restall, James Stephenson, H. J. Stroebel, Louis Wolf, W. H. Woodbury.

The Emergency Transportation Act of 1933 has affected the valuation procedure through the amendment of Paragraphs (f) and (g) of Section 19a (Valuation Act) of the Interstate Commerce Act. The change can best be shown by the following comparison:

*Section 19a as amended February 28,  
1920, and June 7, 1922*

"(f) Upon the completion of the valuation herein provided for, the Commission shall thereafter in like manner keep itself informed of all extensions and improvements or other changes in the condition and value of the property of all common carriers, and shall ascertain the value thereof, and shall from time to time, revise and correct its valuations, showing such revision and correction classified and as a whole and separately in each of the several States and Territories and the District of Columbia, which valuation, both original and corrected, shall be tentative valuations and shall be reported to Congress at the beginning of each regular session."

*Section 19a as amended February 28,  
1920, and June 7, 1922*  
(Cont'd)

"(g) To enable the Commission to make such changes and corrections in its valuations of each class of property, every common carrier subject to the provisions of this Act shall make such reports and furnish such information as the Commission may require."

*Section 19a as amended June 16, 1933*

"(f) Upon completion of the original valuations herein provided for, the Commission shall thereafter keep itself informed of all new construction, extensions, improvements, retirements, or other changes in the condition, quantity, use and classification of the property of all common carriers as to which original valuations have been made, and of the cost of all additions and betterments thereto and of all changes in the investment therein, and may keep itself informed of current changes in costs and values of railroad properties, in order that it may have available at all times the information deemed by it to be necessary to enable it to revise and correct its previous inventories, classifications, and values of the properties; and when deemed necessary, may revise, correct, and supplement any of its inventories and valuations."

*Section 19a as amended June 16, 1933*  
(Cont'd)

"(g) To enable the Commission to carry out the provisions of the preceding paragraph, every common carrier subject to the provisions of this Act shall make such reports and furnish such information as the Commission may require."

The foregoing amendment and consequent reduction in appropriation has resulted in radical changes in the force and organization of the Bureau of Valuation, Interstate Commerce Commission, and the Director and Supervisors of this organization are making earnest efforts to reduce the expenditures for valuation both by the Commission and by the carriers. On account of the revision in the Transportation Act above quoted, there is a tendency to minimize the future importance of the property records which

have been inaugurated under the activities of Valuation Order No. 3. Under the revised section, the Commission is required to "keep itself informed of new construction, extensions, improvements, retirements, or other changes in the condition, quantity, use, etcetera," and at the present time, with the exception of those roads which *were* subject to recapture, the current requirements of Valuation Order No. 3 have not been materially reduced.

The Depreciation Order, the tentative revised classification, and Valuation Order No. 3 are so closely tied into each other that activities with respect to one should be closely coordinated with the activities of the others if economical handling is obtained. Ordinary accounting for property changes will not preserve the integrity of the engineering property inventories which have been made at great expense, and these records, so essential to accounting involving depreciation, should be maintained as an ordinary requirement to record the physical property of a railway company.

They have already been proven of great value in determining retirement information, in the many studies of consolidations and coordination of property; and will be a first requisite of Depreciation accounting. While the expense of initial preparation is great, many roads have found the current maintenance to be nominal and this Committee believes the railways will be amply compensated for their continued maintenance.

## Appendix I

### (E-2) METHODS USED IN RECAPTURE PROCEEDINGS

Chas. Silliman, Chairman, Sub-Committee; A. Anderson, H. T. Bradley, E. S. Butler, C. A. Knowles, J. R. Leguenec, Jr., W. S. McFetridge, E. W. Metcalf, James Stephenson, W. H. Woodbury.

Since the completion of the Committee's report appearing on page 246 of Vol. 34 of the Proceedings, Congress has made important changes in the Transportation Act.

By its Act of June 16, 1933 the Recapture Clause, Section 15a of the Interstate Commerce Act, was repealed and payments made thereunder ordered returned to the carriers.

The various recapture hearings that were set were pushed along until in May, when the passage of the repeal act being so imminent, they were suspended.

## Conclusion

Your Committee desires to report the conclusion of the subject assigned and recommends its discontinuance.

## Appendix J

### (F-2) DEVELOPMENTS UNDER I.C.C. ORDER NO. 15100—DEPRECIATION CHARGES OF STEAM RAILWAY COMPANIES

J. H. Hande, Chairman, Sub-Committee; E. Y. Allen, B. A. Bertenshaw, A. M. Blanchard, E. V. Braden, H. T. Bradley, R. R. L. Bullard, V. H. Doyle, James Erskine, W. W. James, W. R. Kettenring, P. R. Leete, Henry Lehn, A. T. Powell, H. L. Restall, F. C. Sharood, H. J. Stroebel, G. R. Walsh, Louis Wolf.

The situation with respect to depreciation accounting remains unchanged from that reported at the last convention of this Association. The tentative draft of the new classification of accounts embodying depreciation accounting has not been made final and effective. This Committee is continuing its development of recommended procedure

under the provisions of the tentative draft of the classifications, and proposes to bring that recommended procedure into line with the final text of the classification as soon as it is published. That work is proceeding and, it is hoped, will produce results of value to the Association, if and when the regulations are made effective.

## Appendix K

### (F-3) METHODS FOR AVOIDING DUPLICATION OF EFFORT AND FOR SIMPLIFYING AND COORDINATING WORK UNDER THE REQUIREMENTS OF THE INTERSTATE COMMERCE COMMISSION

F. C. Sharood, Chairman, Sub-Committee; H. T. Bradley, V. H. Doyle, C. C. Haire, F. C. Kane, C. A. Knowles, W. M. Ludolph, Chas. Silliman, D. W. Smith, H. J. Stroebel.

The situation with respect to the rendition of a final report on this subject remains practically the same as that reported at the convention of this Association in 1933. Efforts have been made with the hope of securing recognition of this Association as a carrier agency.

Under date of March 7, 1933, the Chairman of Committee XI addressed a letter to the Board of Direction of the Association in which he placed the problem of securing the cooperation of other carrier agencies in the work being undertaken by this Sub-Committee frankly before the Board and asked assistance.

The Board of Direction discussed this letter at a meeting on March 13, 1933, and directed the President of this Association to discuss the matter with the President of the American Railway Association.

Shortly after April 1, 1933, the President of this Association had a conference with the President of the American Railway Association, who requested that the recommendation of this Association be definitely placed before him in writing.

This was done and recommendations made somewhat as follows: The President of the American Railway Association to call a conference of representatives of the American Railway Association, Engineering Division (A.R.E.A.), the Railway Accounting Officers' Association, and the Presidents' Conference Committee. There were to be five representatives from each of the foregoing organizations appointed to attend this meeting and through discussion to ascertain if anything could be accomplished by the formation of a joint committee, and make such recommendations as might be appropriate.

It is expected that this joint committee will be organized and sponsored by the A.R.A. at the opportune time.

Attention is called to an important development during the year when the "Emergency Transportation Act, 1933," approved June 16, 1933, in Title II, amended certain sections of the "Interstate Commerce Act." By Section 205 of the Emergency Transportation Act, 1933, Section 15a of the Interstate Commerce Act is amended so as to remove from Paragraph 2 of Section 15a, the requirement that rates shall be fixed to enable carriers to earn a "fair return upon the aggregate value of the railway property of such carriers held for and used in the service of transportation," and by striking out, in their entirety, Paragraphs 3 to 18, inclusive (Recapture Clauses). Section 206 of the "Emergency Transportation Act, 1933," provides for the termination of all proceedings in connection with recapture and the return of all moneys which had been paid by carriers as the result of such proceedings. Section 208 of the "Emergency Transportation

Act, 1933," amends Paragraphs (f) and (g) of Section 19a (Valuation Act) of the "Interstate Commerce Act." This change is specifically commented upon in the report under Appendix H relating to keeping up-to-date the valuation.

Another important development took place at the convention of the Railway Accounting Officers' Association in Chicago on last August 30th and 31st. Director Lewis of the Bureau of Valuation of the Commission talked informally to the General Accounts' Committee of that organization. During the course of his remarks, Director Lewis appealed for suggestions with respect to the modification and simplification of Valuation Order No. 3.

Since the above took place the Committee on Valuation Accounting from the Accounting Officers' Association is understood to have been given the duty of advising the Bureau of Valuation of the carriers' attitude and are now actively engaged in conferences with the accounting and engineering sections, with the thought of securing reductions in valuation requirements. It is significant that, while the Bureau is using joint engineering and accounting minds in these discussions, yet the carriers are not. It is hoped that the A.R.E.A. will be recognized and be permitted to take part in forming rules and regulations covering future accounting practices.

\* Died October 30, 1933.

### *To the American Railway Engineering Association:*

Your Committee on Water Service and Sanitation respectfully presents below its report to the Thirty-fifth Annual Convention on the following subjects:

- (2) Cause and Extent of Pitting and Corrosion of Locomotive Boiler Tubes and Sheets (Appendix A).
- (3) Methods and Value of Water Treatment, Summarizing Possible Savings Effected (Appendix B).
- (4) Developments in Pipe Joints (Appendix C).
- (5) Essentials of Mosquito Control (Appendix D).
- (9) Disinfectants, Fumigants, and Cleaning Materials (Appendix E).

It is the recommendation of your Committee that the above reports be accepted as information.

Progress is reported on the following subjects:

- (1) Revision of Manual.
- (6) Design and Maintenance of Track Pans for Locomotive Water Supply.
- (7) Methods for Analysis of Chemicals Used in Water Treatment.
- (8) Progress being made by Federal or State Authorities on Regulations Pertaining to Railway Sanitation.

Respectfully submitted,

THE COMMITTEE ON WATER SERVICE AND SANITATION,

R. C. BARDWELL, *Chairman*.

### James Haller Gibboney

---

It is with profound regret that your Chairman announces the death of J. H. Gibboney, Chief Chemist, Norfolk & Western Railway, on October 30, 1933.

Mr. Gibboney has been a tower of strength to the Water Service and Sanitation Committee, and his passing leaves a vacancy that will be difficult to fill.

Mr. Gibboney was appointed a member of the Water Service Committee in 1931, serving thereon until his death.

He was President of the American Society for Testing Materials in 1926-27, and Chairman of the Committee on Arrangements of this Association in 1933.

Mr. Gibboney was born at Wytheville, Virginia, on January 26, 1879, and was admitted to membership in the American Railway Engineering Association in 1911.

He was loyal to obligations and responsibilities assumed in the work of the several scientific and professional organizations to which he belonged, and in all of which he became an effective force and leader. His habit of mind, his industry, his sound judgment, and his practical conclusions on all topics submitted to his analysis made him an invaluable addition to the working force of any organization.

Those members who served with Mr. Gibboney will remember always the calm judgment and clear, intellectual analysis he brought to bear upon the many important questions which frequently arose in the Committee and to what extent his opinion and counsel were awaited.

Mr. Gibboney was by nature kindly and genial, inspiring the respect of all with whom he came in contact, and courteous in his bearing always. While he stood upon an eminence professionally reached by but a select few, he will be missed not alone by those of equal or similar attainments, but more especially by those among the lower ranks of the profession, to whom he was ever ready to extend a willing hand, and give wise counsel and assistance in reaching a higher plane of usefulness, and this was true as well in his relation to those with whom he worked and walked in his daily life, outside the sphere of the professional activities.

## Appendix A

**(2) CAUSE AND EXTENT OF PITTING AND CORROSION OF  
LOCOMOTIVE BOILER TUBES AND SHEETS**

J. H. Davidson, Chairman, Sub-Committee; W. M. Barr, R. E. Coughlan, B. W. DeGeer, J. H. Gibboney, E. M. Grime, J. J. Laudig, M. E. McDonnell, H. L. McMullin, O. T. Rees, R. M. Stimmel, C. P. Van Gundy, R. S. Wilson, J. B. Young.

There have been no important developments in the theoretical aspects of this subject since the last report of this Committee. The basic and fundamental principles involved have been fully discussed in earlier reports appearing in Vol. 23, 25 and 26 of the Proceedings.

As a result of these studies, and experimental work, several proposed methods for inhibiting corrosion have been developed and most of them have been applied in actual service tests over a period of five to ten years.

These proposed remedies have been fully discussed in previous reports and as there have been no new methods of apparent outstanding merit introduced since the last report, the Committee has made an effort this year to collect information from representative railroads as to the present status of pitting and to ascertain what methods have proven most successful in actual service.

From the very start of the work on this subject, it seemed evident that the most available and logical method of attack was to properly condition the boiler water. It was found that by maintaining a sufficient degree of caustic alkalinity in the boiler water, most of the pitting and corrosion could be stopped. Accordingly the Committee developed a formula which serves as a guide. The experimental work by which this formula was developed is explained fully on page 378, Vol. 26 of the Proceedings.

Briefly stated, this formula provides for a caustic alkalinity in the boiler water equal to from 10 to 15 per cent of the total dissolved sodium sulphate and sodium chloride contained in the water.

Information collected this year shows that this is at the present time the outstanding method for inhibiting pitting and corrosion and that practically every railroad that has used this method under competent supervision has succeeded in greatly reducing the damage sustained on account of pitting and corrosion. The fact that this method also eliminates scale formation on heating surfaces adds to its popularity.

The use of corrosion resistant alloys in the manufacture of boiler tubes, flues and sheets has also been given considerable attention and many service tests have been conducted with these materials. Reports from various railroads indicate that to date these alloys have not generally proven economical. New alloys are being developed, and these should be given careful consideration as it is entirely possible that an alloy possessing the necessary qualifications will be eventually produced.

The counter electric potential method of preventing pitting and corrosion has proven beneficial in some cases, especially if the character of the water is such that removal of scale forming elements is not required. Since this method does not provide for removal of incrusting matter in the water it is in most cases advisable to use chemical treatment for this purpose and therefore more economical to properly regulate the treatment to also take care of the pitting.

The use of open feedwater heaters, protective coatings and many other proposed remedies for pitting have been tried with varying degrees of success, but none have thus far proven as dependable and economical as proper conditioning of the boiler feedwater.

Often two or more of the proposed methods can be combined with beneficial results.

One important fact deduced from information collected by the Committee is that it is very important to properly protect boilers of stored locomotives from being damaged

by pitting and corrosion. Boilers stored in good condition have been found to have practically the entire set of tubes rendered useless by corrosion after storage period of from two to four years.

This is an important matter when so many locomotives are stored in good order as has been the case in recent years.

Climatic conditions play an important role in this sort of corrosion, it being extremely troublesome in localities near the seashore or where humidity is usually great. Flue mileage records of locomotives that have been stored several months instead of being worked continuously between flue renewals almost invariably make fewer miles between resetting of flues than those that have not had their service time interrupted by periods of storage.

While the care of boilers of stored locomotives does not usually come under the supervision of water supply engineers, yet it behooves those charged with the responsibility of providing suitable water for boilers to see that all concerned are informed regarding the possibility of damage to boilers of stored locomotives, to the end that the quality of the water will not be unjustly charged with the trouble which develops on account of pitting and corrosion in such boilers after resuming active service.

On page 270, Vol. 33 of the Proceedings, this Committee has described methods recommended for protection of boilers of stored locomotives. These methods, with variations to meet local conditions, are being used by many railroads at the present time. Experiments are being made with other methods. Your Committee feels that economies that may be effected by properly protecting the boilers of stored locomotives warrant more serious consideration by all concerned than is being generally given at present.

## Appendix B

### (3) METHODS AND VALUE OF WATER TREATMENT WITH RESPECT TO ESTIMATING AND SUMMARIZING POSSIBLE SAVINGS EFFECTED

R. E. Coughlan, Chairman, Sub-Committee; W. M. Barr, R. W. Chorley, J. H. Davidson, B. W. DeGeer, R. N. Foster, J. P. Hanley, J. H. Gibboney, R. L. Holmes, C. P. Richardson, R. M. Stimmel, H. W. Van Hovenberg, J. B. Wesley.

During the past year, your Committee has endeavored to summarize the monetary value of the various methods of water treatment with especial reference to the results obtained by the various railroads in the conservation of material, which was formerly destroyed by the use of unsuitable water; also to investigate the increased life of the locomotives as well as the additional work performed by such boilers, with the present reduced forces and shop expense.

While it has been a physical impossibility to obtain records of definite value from all of the larger railroads, sufficient information has been obtained to show the decidedly gratifying results now being obtained as a result of the installation of the various methods of correcting unsuitable water. A typical case of this nature on one of the larger Western railroads shows:

| <i>Five-year period</i> |                               |                       |
|-------------------------|-------------------------------|-----------------------|
| Application of          | new fireboxes .....           | Reduction 89 per cent |
| "                       | " new side sheets .....       | " 91 per cent         |
| "                       | " new back flue sheets .....  | " 84 per cent         |
| "                       | " new front flue sheets ..... | " 96 per cent         |
| "                       | " new two-inch flues .....    | " 83 per cent         |
| "                       | " new superheater flues ..... | " 84 per cent         |

Storage of serviceable power has undoubtedly deferred considerable heavy repairs on all of the railroads, but in order to ascertain if possible the savings that could be attributed to water treatment, a study was made of the comparison of the reductions made necessary because of business conditions, between the mechanical repairs and the boiler repairs. It was found that the boiler repairs during this time showed a reduction of 24 per cent greater than the reduction in mechanical repairs as compared to normal operating conditions. Undoubtedly improved water conditions were responsible for this reduction.

Information now available shows that practically all of the large railroads equipped with water softening facilities are now operating boilers from 15 to 30 days between boiler washings as compared to the seven-day washout period of a few years ago. The locomotives are all actually operating a greater mileage daily so that the total mileage between boiler washings, combined with the longer runs, shows an increase of over 300 per cent as compared to former practice.

Possibly the most gratifying results shown on all of the larger railroads during the past year have been in the increasing number of extensions granted by the Federal Bureau of Steam Locomotive Inspection on locomotives that have operated the four-year period and which locomotives because of the excellent condition of the flues and boiler sheets are in condition to operate an additional year. These extensions are only granted after actual inspection by the Federal inspectors when in their opinion the claims of the railroads are justified. Without suitable water being supplied to the boilers these extensions would be impossible and the actual savings to the railroads because of these extensions return the cost of the investment in water softening facilities in a short time. On some of the railroads additional extensions have been granted after five years' operation which results in further savings formerly entirely out of the question because of the condition of the boilers prior to installation of water softening facilities.

Because of the general unsettled condition prevailing throughout the country which has affected railroad construction in particular, very few additional water treating facilities have been added to the railroads during the past year and while the programs of the various railroads for water softening have been temporarily deferred, the facilities now in service have proven to be one of the main factors in enabling the railroads to operate under decidedly adverse circumstances, so that with the resumption of normal operating conditions and more favorable income additional facilities will show decidedly favorable returns in districts which as yet have not been equipped to supply suitable water.

## Appendix C

### (4) DEVELOPMENTS IN PIPE JOINTS

R. L. Holmes, Chairman, Sub-Committee; B. W. DeGeer, C. H. Fox, E. M. Grime, J. P. Hanley, A. W. Johnson, W. B. Nissly, A. B. Pierce, A. E. Willahan, H. E. Silcox.

#### History

The transportation of water dates back to about 3000 years B.C. The only materials available which could be used for this purpose were wood, stone, lead and pottery; and doubtless the engineers of that time adopted the most economical method of crossing depressions, which was the conduit or aqueduct supported on arches.

The Romans and Greeks well understood the principle of the inverted siphon, one of which was constructed in the works at Lyons, France, which consisted of nine miles of lead pipe, varying in diameter from twelve to eighteen inches and working under a head of two hundred feet.

The lead pipe was produced by working the material into sheets and bent round a core, forming a lap joint and soldered. One end of each section of pipe was expanded sufficiently to form a telescopic joint and on laying the end lap was soldered.

Many of the chief cities of the Roman Empire were served by aqueducts, some of which were forty miles in length, including several thousand feet of tunneling. Rome was at one time supplied from fourteen different aqueducts, the first of which was constructed about 312 B.C.

The distribution of water in this age was by no means general. From the aqueducts the water was passed into large reservoirs or cisterns; thence through lead, stone or clay pipe to smaller cisterns, and to fountains, baths and public buildings. The general public obtained their supply from the fountains.

The development of modern waterworks began in Europe and British Isles during the latter part of the Sixteenth Century A.D., but little progress was made until 1761, during which time pipe of stone, wood, cast lead and pottery was used in laying water mains.

Quoting Professors Turneure and Russell—

"For many years the larger pipes were usually of wood, made by boring out logs to a diameter of six or seven inches. Cast iron pipes came into general use about 1800; and in 1820 the New River Company of London replaced its wooden mains with cast iron ones at a cost of \$1,500,000. At one time this company had about 400 miles of wooden pipe in use, and often as many as ten lines of pipe were laid side by side to form a single main."

The first cast iron pipe of which we have record was made at Versailles in 1664, but due to its cost, its use was very limited until 1738. This pipe was made in relatively short lengths (approximately 39 inches) the ends of which were flanged, octagon in shape, and bolted, using a lead gasket. Some trouble was experienced through the rusting of bolts, which permitted the joints to leak.

The first general waterworks system to be constructed in America was at Boston in 1652. Following the practice of Europe, bored logs were used until about 1817 when a small quantity of cast iron pipe, bell and spigot joint was imported from England, replacing some wood pipe then in service at Philadelphia.

Throughout the ages the weak link has been the joint, the result of which no doubt is responsible for the varied designs.

### Joints and Their Development

The mortised and tenon joint predominated in ancient lines of stone, pottery, and wood, while telescopic, soldered applied to the rolled lead and flanged joints applied to cast lead.

### Screw Joints for Wrought, Steel and Cast Iron Pipe

Wrought iron tubes were first made into gun barrels. The metal was hand hammered into sheets, then formed into cylinders and lapwelded over a mandrel. This practice began in the thirteenth century and continued to about 1824, when James Russell patented the butt weld process which was improved by Cornelius Whitehouse in 1825, by using the bell or die through which the plate or skelp was drawn to form the cylinder.

Steel tubing, both butt and lapwelded longitudinal joints, was first manufactured in 1887, or about 17 years after the invention of the Bessemer converter.

Joining together the tubes to create a pipe line was first accomplished by William Murdock at London in 1815 when he screwed together a quantity of old musket barrels to convey coal gas from the generators to various points for burning. From this time

to 1862 each manufacturer of tubing had his individual specifications covering thickness of wall, diameter of pipe and thread size, when Robert Briggs formulated the dimensions of pipe threads, and compiled a table giving the normal size, the exact diameters and number of threads per inch for all sizes of pipe up to 10 inches. These formulas and tables were subsequently adopted as standard for the manufacture of all tubes and pipes up to 15 inches in diameter and are now known as "American Standard"—Plate A, Fig. 1. There are numerous other screw joints in use, sketches of which are shown on Plate A and A1, Fig. 2 to 20, which have a special service, such as is required in the oil or gas industry, well drilling, casing, etc., although these joints may be used in water lines.

### Cast Iron Screw Joints

Cast iron screw joints, American standard thread, are now available in 6-ft. lengths, varying in diameter from  $1\frac{1}{2}$  to 6 inches inclusive.

### Screw Flanged Joints for Wrought or Steel Pipe

The screw flanged joint is usually used in lines of greater diameter than three inches. The principal advantage in this type of connection is the ease and readiness with which sections of the line may be removed or replaced. For excessive pressures, it has been found advisable to weld the flange to the pipe after screwing on, thus becoming a part of the pipe itself. Another very popular flanged joint is the Van Stone, created by slipping flange over the smooth end of pipe, which is then heated, upset and flared hot, at right angles to the pipe itself. To insure a tight joint the flared ends of the pipe are faced, so that when the pipe is in position the ends will fit snug against the gasket—Plate C, Fig 26.

### Riveted Joints for Wrought or Steel Pipe

Normally used is the butted-and-strapped and bump joint. The first is made by butting the two pipe ends together, covering the joint with a snug fit slip sleeve or strap externally or internally, the former preferred, and then rivet and calk. The bump joint is made by expanding one end of the pipe for a short distance to slip over the other, then rivet and calk. Riveted joints are not generally used in lines of less than 28 inches in diameter.

### Welded Joints of Wrought and Steel Pipe

Welding of wrought and steel pipe joints began about 1910, but little progress was made until 1914 when trunk line construction began. During the past ten years hundreds of miles of eight to twenty-inch welded steel lines have been laid for conveying oil, gas and gasoline from the mid-continent fields to points North and East.

Until recently welding rods of so-called Norway iron were used, which has a tensile strength of 47,000 lb. per sq. in. for single vee welds and 52,000 lb. per sq. in. for double vee welds. Obtainable today are rods which have a tensile strength of 56,000 lb. per sq. in. for single vee welds and 60,000 lb. per sq. in. for double vee welds with consistent regularity by welders of average ability.

A larger portion of the trunk lines in service today are the acetylene welded, the cost of which is approximately 45 per cent of the screw joint type. The price of welding depends upon the fluctuation of labor and material cost, but for estimating purposes the following may be used, which covers cost of materials and labor in welding only, using standard weight pipe, butt welds, the pipe being previously beveled.

|                                                                |   |   |    |   |   |   |       |   |   |
|----------------------------------------------------------------|---|---|----|---|---|---|-------|---|---|
| 2 inch to 6 inch in diameter — 12¢ per inch diameter per joint |   |   |    |   |   |   |       |   |   |
| 7                                                              | " | " | 12 | " | " | " | — 15¢ | " | " |
| 14                                                             | " | " | 30 | " | " | " | — 20¢ | " | " |

Electric welding is used, and it is reported that with the new process of electric welding, a tensile strength of 70,000 lb. per sq. in. is obtainable, with an elongation of 30 to 35 per cent in two inches. The Committee was unable to obtain definite figures as to cost of this type of welding.

### Welded Cast Iron Pipe

The use of welded or brazed cast iron joints began about 1921, using the collar type joint made by depositing a bronze collar around the abutting ends of the pipe, using the acetylene process. This type of joint proved successful in so far as tightness was concerned but failures began to occur with the approach of the first winter following installation, due to the pipe breaking adjacent to weld.

The next experiment was by using the vee type bronze weld, but this joint developed only about 40 per cent of the pipe strength. Failure occurred along bevel line.

In 1924 the bevel-overlap joint was used with success. This type of joint develops the strength of the pipe up to 4 inches in diameter.

In 1926 the shear-vee bronze weld type of joint was developed, which is claimed to be 100 per cent efficient in sizes up to 8 inches in diameter.

Welding materials other than bronze have been used, but tobin bronze rods are so far found to be the best. Experimental work conducted on Pacific Coast in 1921 by Messrs. Bridge and Thompson indicated a 4-inch cast iron pipe was the largest with which cast iron welding rods could be used without preheating or annealing. Special care should be used in obtaining a true alinement prior to welding, and in backfilling and tamping the lower half of pipe to prevent beam action.

Expansion and contraction is an important factor in laying welded cast iron joints, but actual field test during 1927 indicated that the common formula for calculating expansion does not apply on buried lines. Two sections of line were used in the test, one having a length of 143 feet, the other 450 feet. In the former and with a maximum range of temperature of 120 degrees the measured elongation was 76 per cent of the calculated. In the latter case and a maximum range of 82 degrees the measured elongation was 24 per cent of the calculated.

The formula used in calculating follows—

$$\text{Elongation in feet} = \text{length} \times \text{range} \times \text{coefficient (.000006)}$$

Typical cross-sections of brazed or welded cast iron joints, and indicating points of failure are shown on Plate C—Fig. 22 to 25 inclusive.

On plate B and B1 are shown 72 different kinds of cast iron joints—Fig. No. 1 showing the first joint of record.

Beginning with Fig. 35 to and including Fig 53—Plates B and B1 all of which may be used with steel or wrought pipe.

### Bell and Spigot Joint Cast Iron Pipe

The first cast iron pipe of which we have record was made at Versailles in 1664 but cast iron was not generally used until 1738, when the bell and spigot joint was first introduced.

Many different joint materials and combinations of materials have been used in laying cast iron pipe, but lead seems to have been most generally used up to a few years ago. The least expensive and as reliable as any is standard Portland cement and dry jute or oakum.

FIGURE 72

The cement joint passed its experimental stage from 1913 to 1915 during which time varying combinations were tried, none proving as efficient, however, as the joint shown on Plate B1—Fig. 69 and 70. The cement and jute joint is suitable for use under most conditions applying to lead or joint compositions. The secret of the cement joint is in getting a good yarning job. The bell and spigot end should be thoroughly cleaned. The spigot well centered to give an equal distribution of jute and cement. In applying the customary rings of jute, the ends should lap and the jute compressed (by driving) to depth thickness of approximately  $\frac{3}{4}$ -in., then prepare and add the cement.

Many cement joint advocates recommend keeping pressure off of green joints for 24 to 48 hours. This delay is not necessary for there is not sufficient moisture added to the cement to complete hydration until the pressure is on the line and the water slowly percolates through the jute. Many joints in moderately low pressure lines have been examined after two years' service and found to contain two to three inches of unset cement. On lines of 100 to 180 lb. pressure all joints examined indicated complete set.

Three all-cement joint lines have been under observation for three years, one of which is seventeen miles in length composed of 10 and 12-inch pipe working under a maximum pressure of 165 lb. Another line 12 miles long composed of all 10-inch working under a maximum pressure of 170 lb. The third line five miles in length composed of 8 and 10-inch pipe working under a maximum pressure of 150 lb. These lines were recently tested for leakage, neither of which showed a loss of more than 1 GPM. The lines are in a semi-arid country where the atmospheric temperature varies 132 degrees.

When these lines were laid a saving of \$22,000 was effected over the next cheapest jointing material considered.

### Mechanical Cast Iron Pipe Joints

On Plates B and B1—Fig. 34 to 66 are shown about 32 different kinds of mechanical joints, some of which have been thoroughly tested. See 1932 report of Peoples Gas Light & Coke Company and the United Gas Improvement Company cooperating with the American Gas Association. Also see report No. 706 of American Gas Association Testing Laboratory as of February 22, 1933.

### Cast Iron Bell Joint Clamps

Two means are used to repair leaking bell joints. First, to either recalk or remake the joint or, second, to apply leak clamps, which are shown on Plate C—Fig. 1 to 21.

### Fire Hose Couplings

Through the efforts of the National Board of Fire Underwriters a National Standard has been adopted by a majority of the States covering fire hose couplings. Prior to about 1919, the fire fighting equipment, especially hose connections of one municipality were not interchangeable with another, the result was that in lending aid, much valuable time was lost in making adapters, before assistance could be given. Texas is reported to be the only state that is 100 per cent standardized.

### Transite Pressure Pipe and Couplings

This product is a mixture of Portland cement and asbestos fiber and contains no other reinforcement. It has been manufactured in Italy for about fifteen years, and now obtainable in America. The length of joint is ten feet, for diameters of 2 to 7 inches inclusive, and in 13-foot lengths for diameters of 8 to 36 inches.

The weight per cubic foot is about 28 per cent of sand cast pipe and has five classifications, namely, A, B, C, D, and E, following the practice of the American Waterworks Association. The manufacturer recommends Simplex Coupling, Plate C—Fig. 29, but

will furnish if the purchaser so desires, Dresser, Dayton or Flanged Couplings, and advises against the use of rubber ring where temperatures of over 175 deg. F., are encountered or in handling solvents of rubber in which event special gasket material will be furnished.

### Reinforced Concrete Pressure Pipe

Until about ten years ago, reinforced concrete pipe was principally used in sanitary and storm sewer work, but since that time and with the centrifugal process a very dense pipe is produced that has a lower resistance to flow of water than steel or iron.

On Plate C—Fig. 27, are shown two types of joints for pipe diameters 21 inches and above and Fig. 28 for pipe 18 inches and below.

The manufacturers of centrifugal concrete pipe guarantee seepage losses to less than 200 gallons per inch diameter, per mile, per day of 24 hours. A number of tests have been made, none of which exceeded the allowable, and in many cases the loss was as low as eight per cent of the allowable.

This Committee desires to express to the American Gas Association, the American Petroleum Institute, Pipe and Joint Material Manufacturers our appreciation for information used in this report.

## Appendix D

### ESSENTIALS OF MOSQUITO CONTROL

By H. W. VAN HOVENBERG

A considerable portion of the population of the United States is not interested directly in the problem of mosquito control from the standpoint of protection from mosquitoes that carry disease, such as malaria fever, because of the geographical limits of the disease habitat, notwithstanding a better appreciation of the South's malaria problem would possibly be to the advantage of the Northern investor in many ways. The entire population does concern itself in the control of mosquitoes to eliminate the mosquito as a pest, so that in the past fifteen years we have seen many mosquito abatement districts formed which may be classed as major engineering operations, involving the spending of hundreds of thousands of dollars annually.

Control of the pest mosquito is obviously for human comfort, both in dwellings and in the open, and for the protection of laborers, both day and night. In some sections of the country live stock and poultry have to be given some measure of protection. The creation of some resort areas has been dependent on the control of the mosquito pest. Cities are now engaging engineers to direct mosquito control work in order that public parks, swimming pools, golf courses, and playgrounds may be made enjoyable.

Along the New Jersey coast, where there are hundreds of thousands of acres of marsh lands producing mosquitoes, abatement districts have not only controlled the pest at unbelievably low costs, but have enhanced property values to much more than pay for the engineering work involved. These results were obtained by the development of power ditching machinery, use of tide gates and pumping plants, and chiefly by an excellent understanding of the problem by the mosquito abatement officials.

A new interest in the control of disease carrying mosquitoes is in the studies that are being made to forestall the bringing into this country of new varieties of mosquitoes, or of infected mosquitoes, that are proven carriers of malaria or of yellow fever, by airplane or ship, or of the diseases by infected humans at the borders.

The control of mosquitoes that transmit disease may be instituted to prevent the possibility of a disease, such as yellow fever, from getting into the country. For ex-

ample, we have the mosquito *Aedes aegypti* breeding in abundance over most of the United States, and ready to spread yellow fever should a person infected with the disease enter the country and be bitten by these mosquitoes, and the disease via the mosquito carried to well persons. A control project may be planned to stamp out an incipient flareup of yellow fever, or malaria, or dengue, or may be planned to eradicate disease where it has been long established. The engineering methods for these different conditions of control will vary.

Changes in natural topography, such as the impounding of large or small bodies of water, have brought a change in the varieties of mosquitoes, and in the case of malaria fever, have been responsible in many instances for the rapid spreading of the disease, so much so that a number of states now have laws governing the conditioning of water power sites. A considerable amount of mosquito research work has been done in this country, chiefly by the United States Public Health Service, in order to arrive at methods that should apply to areas embraced in impounded water projects. Both minor and major drainage projects, particularly in the Southern states, have complicated the spread and the control of malaria fever.

Our railroads have their mosquito problems, both from the standpoint of pest and disease, direct and indirect. Railroad labor is affected by both pestiferous and disease-carrying mosquitoes. It is quite impossible for any laborer to return a decent output for his hire if he is kept awake at night by pest mosquitoes, and likewise utterly impossible for him to return even a feeble effort for his pay if he is suffering with malaria.

Indirectly the railroads operating in the malaria belt suffer from decreased production from farm and factory in those sections where the disease is rampant, both by decrease in freight haul from such places and to such places, for such communities neither produce nor have the surplus from their labor to purchase. The mutual interest of railroads and communities is intensified in those sections in which malaria is still a serious public health problem, and it is undoubtedly true that no other preventable disease affects railroad operation in the South as does malaria. How serious this problem is, is reflected in a study of railway hospitals in the South, which showed that fully one-third of all hospital medical cases were chargeable to malaria, not including the many seriously complicated surgical cases, or the larger number of employees getting relief from malaria through local surgeons or other agencies.

For any mosquito control problem, the solution requires a knowledge of the kinds, habits, flight range, seasonal breeding, and other characteristics of mosquitoes, and a thorough understanding of field engineering methods for their control, including ditching by hand, machine, and dynamite; oiling, dusting with Paris green; brushing and clearing of water courses; inner ditching and lining; use of mosquito larvae eating fish; screening; and prophylaxis. Since the World War this work of controlling mosquito production has given employment to many engineers and others, and the science of control has progressed to the point where it may be called a profession. Many of our engineering associations have sections, or scientific reports, devoted to the subject. Similar to any other engineering project, the control of mosquitoes involves planning, research, organization, and adequate direction.

With particular reference to railroads, the problem of protecting employees from malarial infection is complicated because of the various conditions under which certain groups of them live and work. Bridge and building, extra gang, and other mobile forces, spend much of their time in river bottoms where they are necessarily exposed to hordes of mosquitoes. These men, living in camp cars, usually average about six per cent of the total railroad employees, yet in the South have furnished railroad hospitals with about thirty-five per cent of the malaria cases. Shopmen, most of whom live in

larger communities, comprise about thirty per cent of the employees, and furnish about twelve per cent of the malaria cases. In normal times about twenty per cent of employees are section laborers, and they have usually supplied forty per cent of the hospital malaria cases. These figures have been cited to show the range of infection by groups, and because the method of control of malaria will differ with each group.

Any plan of control should be based on securing the maximum protection for the least cost, and every known method can be applied. For the protection of men employed in shop towns, it will generally be found most expedient to eradicate mosquitoes by drainage, oiling, filling, use of fish, and other field control means. For mobile units, such as Bridge and Building gangs, the first step should be the proper screening of their sleeping and eating quarters with sixteen-mesh wire screens. Locating outfit cars in localities free from malaria mosquitoes whenever possible, swatting mosquitoes in cars, and use of quinine as a possible prophylaxis, will also be effective. Isolation of patients under treatment for malaria, screening of houses, and use of quinine, will generally suffice for protection of employees living in section houses. The above three classes of employees comprise approximately fifty per cent of the total employees of a railroad in normal times, and in the South will furnish better than eighty-five per cent of the railroad hospital cases.

The economy of malaria control in behalf of railroad employees in the South has been amply demonstrated by the pioneer work of the St. Louis Southwestern Railway, beginning in 1917, and by the subsequent adoption of similar work on the Missouri Pacific and the Rock Island railroads. The net result of the railroad malaria and mosquito work has been its spread to practically all cities and towns in the South.

Probably the most outstanding single piece of health legislation in the South is that of the creation of the Texas Malaria Unit designed to bring the story of malaria, and its cause and prevention, to the inhabitants of seventy-two counties, having an area greater than the six New England states. This project was fostered by the East Texas Chamber of Commerce as a purely economic venture, and a state legislative appropriation of \$50,000 made to cover the work for two years, coming to a close September 1st, 1933. The most outstanding achievement in connection with this project was the enlisting of the educational forces of the state, the Parent Teachers' Associations, the Women's Clubs, and of most particular importance, of the Home Demonstration Clubs of farm women, in the study of malaria in schools and in the application of anti-malaria measures about rural homes.

The interest of our railways in mosquito and malaria work is reflected in the information collected by the National Malaria Committee on Engineering in 1930. Fifteen railway systems operating in the South and Southwest, with a total mileage of 74,898 miles supplied the information which is tabulated as percentage of the total miles:

| Railways having some designated person assigned to mosquito and malaria control work          | 39 | Per cent |
|-----------------------------------------------------------------------------------------------|----|----------|
| Railways applying oil in control of mosquitoes.....                                           | 60 | " "      |
| Railways donating and applying oil.....                                                       | 27 | " "      |
| Railways doing right-of-way drainage control.....                                             | 88 | " "      |
| Railways maintaining screened living quarters.....                                            | 85 | " "      |
| Railways distributing quinine to employees.....                                               | 39 | " "      |
| Railways distributing malaria educational bulletins.....                                      | 44 | " "      |
| Railways responding to requests for aid in control work from cities, counties, or states..... | 90 | " "      |

## Appendix E

### (9) DISINFECTANTS, FUMIGANTS, AND CLEANING MATERIALS

W. P. Hale, Chairman, Sub-Committee; W. R. Anthony, J. J. Laudig, O. T. Rees, H. W. Van Hovenberg, J. B. Young.

The subject assigned to the Committee has been deemed of sufficient importance to warrant extended investigations, since the subject covers a wide scope of varied materials of innumerable usages, and represents a considerable expenditure on the part of the various railways. For these reasons, the report for this year will consist of a general outline of the scope of the subject, a differentiation of the terms "disinfection", "fumigation" and "deodorization" and a digest of the more common compounds for the purpose required.

Any complete report on the subject must, of necessity, to be of any value to the members of the Association, contain definite instructions concerning the use of the varied materials, describe the particular compounds for each particular purpose, and detail methods for their successful use economically. This phase of the subject will be taken up in later reports of the Committee.

#### Disinfection

"Disinfection" means the destruction of the agents causing infection. An object is said to be "infected" when it is contaminated with disease producing bacteria. It is "disinfected" by destroying these bacteria, whether they are in the substance or on the surface of that object. Disinfection, then, deals only with destroying the vitality of those minute forms which cause disease. It does not mean the destruction of all the lower forms of animal and vegetable life that may be in or upon an object—that is, sterilization.

Considerable confusion exists between disinfectants and "deodorants". A deodorant is a substance which has the power to destroy or neutralize unpleasant odors, such as those arising from organic matter undergoing fermentation or putrefaction. Such substances must be carefully distinguished from disinfectants. Deodorants are not, necessarily, disinfectants, and disinfectants do not necessarily have an odor. No confidence can be placed on disinfectants simply because they smell of chlorine or carbolic acid, or possess the color of permanganate. Deodorants destroy smells; disinfectants destroy germs. Many of the disinfecting agents are also deodorants, but all deodorizing substances are by no means disinfectants. For example, charcoal will absorb the malodorous gases rising from rotting and fermenting organic matter, but it is inert so far as its power to destroy the cause of the processes is concerned.

Formalin and ozone, on the other hand, are true deodorants and disinfectants, as they combine with the organic matter to form new compounds which are both odorless and sterile. The volatile oils and other substances having a pungent odor are not deodorants, they simply cover up one smell with another.

The ideal disinfectant must first and foremost have a high germicidal power. It must not be rendered ineffective by the presence of organic matter; it must be reasonably stable, so as not to deteriorate under ordinary conditions; it must be soluble in water; it should be harmless to man and the higher animals; it should have the power of penetration; it should not corrode metals, nor bleach or rot fabrics, and finally it should be reasonable in price. Such perfect disinfectants are unknown.

The majority of the disinfectants sold to the public are mixtures of varying quantities of phenolic bodies, especially the cresols, with inert tar oils and an emulsifying

agent such as soap or tar, and sometimes resin or gelatin. These substances all possess a smell distinctive of carbolic acid and are effective germicides. Cresol is prepared from coal tar by collecting the distillates coming over between 140 degrees and 220 degrees C. and then purifying these distillates with solution of sodium hydroxide and hydrochloric acid.

In nature many forces are constantly at work to destroy infection and limit the spread of the communicable diseases. It is the duty of the sanitarian to encourage the use of these natural disinfecting agents; they are: dilution, sunlight, dryness and time. Sunlight is a great destroyer of germ life. Dryness, sunlight and cleanliness are the key-notes of sanitation in the modern acceptance of the term. Cleanliness is a very important ally to the work of disinfection. In fact it lies at the base of all our sanitation measures. Disinfection cannot compensate for the lack of cleanliness and ventilation.

For some time lime has been accepted as one of the best and cheapest disinfecting substances. It has been usually used either as lime or as chlorinated lime. The latter was used as a disinfectant and deodorant long before bacteriology was a science. It has a peculiar composition chemically and is somewhat unstable. Due to its affinity for moisture, which it slowly absorbs from the air, it soon becomes pasty and loses some of its chlorine. It should therefore be kept in airtight containers.

Chlorinated lime came into special prominence due to its use for the disinfection of drinking water and sewage. A surprisingly small amount will disinfect a large volume of water. A clean water may be rendered safe by the addition of 0.1 of a part of chlorinated lime (estimated as available chlorine) to 1,000,000 parts of water. For waters containing organic matter as much as 1 to 5 parts per million may be required.

Rideal and Walker\* in 1903 introduced a method by which they proposed to determine and state in definite numerical terms the value of any disinfectant. This they called the "carbolic coefficient", because carbolic acid is taken as the unit of measurement against which the power of the other substances is compared. It is commonly known as the "phenol coefficient". This coefficient of any substance should be based upon the average of a large number of tests.

A low carbolic coefficient usually means a useless disinfectant. Formalin has a low coefficient, although formaldehyde is a potent germicide. This is due to the fact that the coefficient is based on formalin which contains only 40 per cent or less of formaldehyde. On the other hand it should be remembered that because a germicide has a high coefficient it is no absolute indication that it is a favorable disinfectant in practical work. There are many facts still to be considered, as noted in above paragraphs.

Liquid chlorine has largely replaced chlorinated lime in the disinfection of water and sewage since it has many advantages over the latter. The quantity used can be more accurately controlled; it has constant composition and does not produce sludge or increase the hardness of the water being treated. It is used also for removing taste and odors.

This gas is handled in gas tight pressure cylinders, takes up little space and the ordinary cost of application is less than chlorination with chlorinated lime.

The use of chlorination has been one of the blessings conferred on humanity, since its intelligent use in the field of water supplies has always resulted in marked decreases in typhoid fever and other intestinal diseases.

Formaldehyde in solution is known as formalin. This latter is a very valuable disinfectant with a wide range of usefulness in general practice. It is also a true deodorant. It is not injurious to most articles and not very poisonous. Rosenau states

\* "The Standardization of Disinfectants", *Journ. of Roy. San. Inst.*, 1903.

that "formaldehyde is the most generally useful and one of the best disinfecting gases we have."\*

### Fumigation

Fumigation consists of liberating fumes or gases with the object of destroying germs or vermin, insects, rats, mice, and other small animals, acting as carriers of infection, or destroyers of food products or other matter. The chief fumigants used are hydrocyanic acid gas, carbon bisulphide, chlorine, carbon monoxide, pyrethrum, formaldehyde, and sulphur dioxide. Fumigation cannot take the place of disinfection. It is chiefly useful in preventing the spread of insect-borne diseases, and the destruction or damage to food and other products.

Hydrocyanic acid gas is a cheap fumigant, probably the cheapest effective fumigant known. It is one of the most rapidly fatal poisons known to man. Because of this fact its use as a fumigant is attended by grave hazards to human life. This gas is our nearest approach to the ideal fumigant. It has practically no germicidal action, but is a very strong insecticide.

Sulphur dioxide, generally produced by burning sulphur, is the best gas in the matter of warning of its presence. It is the only nearly safe fumigant known, because in concentrations far below the quickly fatal level it causes severe irritation of the throat and persistent coughing. Sulphur fumigation has almost entirely been abandoned in this country because the gas penetrates so slowly and its results are unreliable. Sulphur dioxide tarnishes metals, rots fabrics, and bleaches pigments, especially when moist. Fumigation with sulphur dioxide may, however, be done with very little damage to property on dry days.

Pyrethrum powder is a popular and much used insect fumigant because it is comparatively cheap and non-poisonous to man and the higher animals. It is also non-corrosive, but unfortunately it has but a feeble action against roaches, vermin, flies, fleas, mosquitoes, etc. It has no germicidal action. Much of the pyrethrum on the market is impure, which further weakens what is at best a feeble insecticide.

Formaldehyde is an irritant gas, irritating the eyes, nose and throat. It is not dangerous to human life unless it is in enormous concentration and then only after long exposure. Rosenau states that "it is not very toxic to higher forms of animal life, but it is the leading germicide. It is not an insecticide. In the strongest concentrations possible it has no effect on roaches, bedbugs and other strong insects."\*

Three substances have lately been developed as fumigants which will probably become widespread in use. These are ethylene dichloride, ethylene oxide, and carbon dioxide. The first named is generally mixed with carbon tetrachloride to remove the fire hazard. These fumigants are much less poisonous than hydrocyanic acid and must be used in much higher concentrations. They are relatively slow in their action, and are relatively more poisonous to insects and warm-blooded animals. These properties permit fumigation with reduced hazard to human life.

In many instances certain types of fumigation are required by Federal statute. One instance is that of cotton freight cars infected with Mexican pink bollworm, a very serious pest to cotton. Several years ago inspection revealed that frequently certain types of freight cars returning from Mexico were likely to be contaminated with cottonseed, and if the cottonseed originated in areas in Mexico where the pink bollworm occurred it was often infested with the larvae of this insect. To guard against further entry of the pink bollworm into this country provision was made for the cleaning of all cars found to be

\* Rosenau "Preventive Medicine and Hygiene".

contaminated with cottonseed, and, as an added precaution, fumigation was required to take care of any larvae which might be present in cottonseed that had escaped detection in the floor, cracks in the walls, and other out-of-the-way places in the cars.

The first fumigation on the Mexican border was performed by the old so-called "pot method" whereby hydrocyanic acid gas was generated inside the car from sodium cyanide, sulphuric acid and water. This method at its best was not entirely satisfactory. When the fumigations were numerous considerable work was involved in attempting to make the cars tight, and naturally the fumigation was limited to box cars only. It was also impossible to reach any cottonseed which was present on the trucks or attached to the outside of the cars. Frequently cars were received in such bad condition that it was impossible to make them air-tight enough for the fumigation to be effective. In order to overcome these difficulties specially designed fumigation houses were constructed. The first car fumigation houses were built during 1919. At the present time there are six such houses along the Mexican border, with capacities varying from 20 cars or less. These houses are constructed of brick, and are so divided by sliding doors that any number of cars from one to the maximum capacity of the house can be accommodated. For several years liquid hydrocyanic acid has been used as a fumigant and satisfactory results have been obtained.†

Some idea of the vast scope of the assigned subject may be obtained from the following outline of correlated purposes for which disinfectants, fumigants, deodorants, and cleaning materials are used on railways, and on which detailed report will be prepared before conclusion of the assignment:

1. Disinfection and/or deodorization of passenger cars, cattle cars, cattle pens, poultry cars, cotton cars, copra and bone cars.
2. Fumigation of grain cars, grain elevators, camp cars, passenger equipment, hotels, eating houses, grain houses, etc.
3. Car cleaning, cuspidor cleaning, washing floors and woodwork and windows, drinking water disinfection, sterilizing water tubs, cisterns or tanks.
4. Cleaning and deodorizing cars or buildings used in handling fish, milk and cream, dressed and live poultry, etc.

All these matters are pertinent to the assigned subject of "Disinfectants, Fumigants, and Cleaning Materials," and will be discussed in future reports.

## REPORT OF COMMITTEE XXII—ECONOMICS OF RAILWAY LABOR

LEM ADAMS, *Chairman*;  
C. W. BALDRIDGE,  
W. R. BENNETT,  
A. E. BOTTS,  
H. A. CASSIL,  
J. I. CATHERMAN,  
C. S. COLVIN,  
J. F. DOBSON,  
WM. ELMER,  
J. A. GORR,  
PAUL HAMILTON,

W. S. HANLEY,  
H. H. HARSH,  
A. C. HARVEY,  
H. I. HOAG,  
C. H. R. HOWE,  
E. T. HOWSON,  
C. A. JOHNSTON,  
C. R. KNOWLES,  
G. M. MAGEE,  
G. M. O'ROURKE,  
J. A. PARANT,

F. S. SCHWINN, *Vice-  
Chairman*;  
J. C. PATTERSON,  
H. E. PERKINS,  
F. R. REX,  
H. M. RIGHTER,  
H. M. STOUT,  
F. M. THOMSON,  
J. G. WISHART,  
C. R. WRIGHT,  
*Committee.*

*To the American Railway Engineering Association:*

Your Committee respectfully presents herewith report covering the following subjects:

- (2) Analysis of operations of railways that have made marked progress in the reduction of labor required in maintenance of way work (Appendix A).
- (4) Methods of reducing work-train service and economies in maintenance expenses effected thereby (Appendix B).
- (5) Programming of bridge and building work (Appendix C).
- (6) Revised plans for outfit cars for maintenance of way employees (Appendix D).
- (8) Gang organization and methods of performing maintenance of way work, including revision of time studies now in the Manual (Appendix E).

Progress is reported on Subjects 1, Revision of Manual; and 7, Economics of methods of weed killing.

### Action Recommended

- (1) That the report under Appendix A be received as information and the subject continued.
- (2) That the report under Appendix B be received as information and the subject be discontinued.
- (3) That the report under Appendix C be approved as recommended practice and printed in the Manual, and the subject be discontinued.
- (4) That the report under Appendix D be accepted as information, the conclusions and plans be adopted as recommended practice and printed in the Manual.
- (5) That the report under Appendix E be received as information and the subject continued.

On Subject No. 3, Effects of recent developments in maintenance of way practices on gang organization, the Committee is unable to develop any additional information at the present time and recommends that the subject be discontinued for the present.

Respectfully submitted,

THE COMMITTEE ON ECONOMICS OF RAILWAY LABOR,

LEM ADAMS, *Chairman.*

## Appendix A

## (2) ANALYSIS OF OPERATIONS OF RAILWAYS THAT HAVE MADE MARKED PROGRESS IN THE REDUCTION OF LABOR REQUIRED IN MAINTENANCE OF WAY WORK

J. A. Parant, Chairman, Sub-Committee; W. R. Bennett, H. A. Cassil, J. F. Dobson, A. C. Harvey, E. T. Howson, C. A. Johnston, C. R. Knowles, J. C. Patterson.

In November, the Committee made its second inspection trip over the Lehigh Valley Railroad.

Considerable additional information on the assignment has been gathered, but not in form to present to the Association this year as a supplement to the 1930 report.

## Appendix B

## (4) METHODS OF REDUCING WORK-TRAIN SERVICE AND ECONOMIES IN MAINTENANCE EXPENSES EFFECTED THEREBY

G. M. O'Rourke, Chairman, Sub-Committee; Wm. Elmer, J. A. Gorr, W. S. Hanley, H. H. Harsh, A. C. Harvey, E. T. Howson, F. M. Thomson.

Among the means to effect economy and increase efficiency that have been investigated by the Committee is the reduction in work-train service for maintenance of way operations. That some reduction has been effected in recent years is generally known. The magnitude of this reduction is, however, not widely appreciated. The total work train mileage of the Class I railways of the United States, as compiled by the Interstate Commerce Commission, is as follows:

*Year Ending  
December 31*

|      |            |
|------|------------|
| 1916 | 46,728,640 |
| 1917 | 44,737,643 |
| 1918 | 45,039,419 |
| 1919 | 36,705,124 |
| 1920 | 41,494,199 |
| 1921 | 25,672,043 |
| 1922 | 27,369,588 |
| 1923 | 37,384,812 |
| 1924 | 32,489,978 |
| 1925 | 33,114,358 |
| 1926 | 37,279,616 |
| 1927 | 36,531,830 |
| 1928 | 33,236,462 |
| 1929 | 35,775,192 |
| 1930 | 24,079,859 |
| 1931 | 13,960,642 |
| 1932 | 8,066,621  |

The figures for 1930, 1931 and 1932 were obviously influenced by the curtailment of operations, as were also those for 1921-1922. If the figures for these years be ignored, and consideration be confined to the more normal years of 1916-1920, inclusive, and 1923-1929, inclusive, the trend can be determined more accurately. Thus, in the five-year period from 1916 to 1920, the average work-train mileage was 42,941,206, while in the seven years from 1923 to 1929, inclusive, the average was 35,101,949. In other words,

in this average interval of eight years, the decrease was 18 per cent, or at the average rate of  $2\frac{1}{4}$  per cent per year.

The above figures include all work train mileage, maintenance of way and otherwise. If it were possible to segregate that employed in maintenance of way operation, it would be shown that the decrease here is relatively greater than the average shown above. The figure given is sufficient, however, to show the trend.

To determine how this has been accomplished, the following questionnaire was sent to 47 railroads of the United States and Canada. Twenty-six replies were received:

1. What reductions have you made in work-train service for maintenance of way operations during the last ten years?
2. What measures have you initiated to effect this reduction:
  - (a) Through the use of track motor cars;
  - (b) Through the use of self-propelled cranes, pile drivers, etc.;
  - (c) Through the more extensive use of local freight or other revenue trains;
  - (d) Through the use of off-track equipment;
  - (e) Through other measures.
3. For what operations are you employing these various measures;
  - (a) With what results?
4. What further substitutions of work-train service do you believe are feasible?
5. For what operations is work-train service still essential?
6. To what extent and in what ways is the use of self-propelled equipment restricted by statute or agreements with employees?
7. How is the ordering out of work trains controlled?

### Reductions of Work-Train Service

Reductions were reported by 25 roads in the use of work trains for maintenance of way operations during the last ten years. One road reported no reduction except that such as was incidental to less work being done this season than in some years past.

Two carriers reported a 75 per cent reduction, one road 72.7 per cent reduction in number, and 73.4 per cent in cost during past seven years; one road 55 per cent, two 50 per cent, one 40 per cent, one 22 per cent and two 20 per cent reduction in work trains during the last ten years.

During the last four years the great reduction in work-train service has been due to curtailed maintenance of way operation. Nevertheless, the use of work trains has been curtailed by very close scrutiny of the operations that had heretofore been handled by special work trains, and other service substituted.

The principal means of reducing work-train service, in reply to inquiry No. 2, are listed below:

| <i>Measures Initiated</i>                      | <i>Railroads Reporting</i> |
|------------------------------------------------|----------------------------|
| Use of local freight trains .....              | 22                         |
| Track motor cars .....                         | 18                         |
| Self-propelled cranes .....                    | 18                         |
| Light extras—to balance power .....            | 13                         |
| Self-propelled pile drivers .....              | 13                         |
| Off-track equipment .....                      | 11                         |
| Cooperation of transportation department ..... | 4                          |
| Highway trucks .....                           | 4                          |
| Closer planning and supervision .....          | 3                          |
| Self-propelled ditchers .....                  | 3                          |
| Narrow-gage cars ditching cuts .....           | 1                          |
| Creosoted cross-ties and switch-ties .....     | 1                          |
| Supply train .....                             | 1                          |
| Contracting work to outside parties .....      | 1                          |
| Use of switch engines in terminals .....       | 1                          |
| Self-propelled derricks .....                  | 1                          |
| Caterpillar trucks and trailers .....          | 1                          |

Practically all of the 22 railroads reporting state that special attention has been given to the use of local freight and other slow revenue trains for the distribution of material along the railroad. In many cases ditching machines were used for several hours daily, where local freight did not require full time to make the assigned run.

By consolidating work of different kinds in certain territories or by holding loads of ballast, etc., until enough cars are accumulated for more than one day's consecutive work-train service, and by providing more than one day's work in the same territory on many railroads, engine and crew may be tied up near the work and considerable deadhead payments can be avoided as compared with having several work-train days at different periods.

### **Balancing Power**

Many railroads have made full use of surplus power in direction of light tonnage for doing work and find this to be one of the most fruitful sources of work train savings. By keeping in close touch with the transportation department and by proper planning of the work, large savings are being effected by using power in the direction of light tonnage.

### **Cooperation Between Maintenance of Way and Transportation Departments**

Four railroads put particular stress on cooperation between the maintenance of way and the operating departments. One of these reported 75 per cent reduction during the past decade by "closer planning and supervision and through better cooperation of the operating department." Another large carrier in the west states that probably the most important factor in reducing work-train service has been the more careful planning and scheduling of the work, enabling more work to be done with less train service.

### **Distribution of Materials**

A railroad serving a congested industrial and mining territory in the east advises that the programming of maintenance work requiring work-train service is highly important. This practice permits the establishment of definite schedules for receiving and distributing materials, for ditching and pile driving, and consequently is a very important factor in preventing waste, and in avoiding duplication of effort. With knowledge of the work planned through the year, the required number of men may be selected and kept in work-train service. Outfit cars are provided, and as a unit they achieve greater efficiency than could ever be attained by "picking up" a section force or a different gang each day. Supervision of work-train service on this railway is supplemented by a staff of technically trained young men, familiar with the maintenance program, whose duty it is also to keep cost records of all work. The benefit of economies thus effected is also reflected in transportation and operating costs.

A western trunk line distributed cross-ties over its entire main line and important branch lines during this year by the use of work train, using an assigned crew. The camp cars were kept in the work train at all times, and by having cross-ties set out in cars in quantities of 10 to 20 cars at a time on sidings where there would be no back-haul. When the assigned trains were operated, the crew was able to tie up at night, and started from that point the next day.

The work was planned for a continuous operation, beginning at one end of the line and working through to the other end and diverging to branch lines in the manner to give the best possible working time. This operation required a lot of planning in advance in order that the ties would arrive at the location where needed in sufficient quantity and sufficiently in advance to prevent delay to tie distribution crew and at the same time avoid unduly tying up equipment.

### Use of Track Motor Cars

The use of track motor cars to avoid or supplement work train service as reported by 20 railroads is as follows:

- To distribute track ties from storage piles to point of use.

- To distribute repair rails, frogs, switches and other track materials used in repairs.

- For the distribution of materials used in repairing washouts; particularly sand bags, riprap, etc.

- To transport large extra gangs to and from work.

- To tow transverse fissure detector car.

- To transport broken or other defective rails and scrap to a central point.

- For moving tie tamping and welding equipment and many other operations that formerly required work trains.

### Use of Self-Propelled Equipment

A large number of railroads reporting advise that the use of self-propelled cranes, pile drivers, etc., has greatly reduced requirements for work trains. These machines are used in many ways; some of the most general uses are as follows:

A locomotive crane is used to take out two cars of rail at a time, and distribute the rail for laying, where distance from sidings is not too great, also pickup rail and fittings after relay.

The self-propelled crane is also used with a clamshell bucket and two dump cars to load rock and similar classes of work.

These cranes are used extensively for handling heavy material about shops, material yards, and reclamation plants.

The self-propelled ditcher is extensively used for cleaning cuts, using two dump cars where material can be disposed of by making only short runs.

Self-propelled pile drivers and erection derricks are very extensively used and have largely displaced the use of work trains in pile driving and heavy bridge erection.

### Delivery and Pickup of Materials and Supplies in Terminals

The delivery and pickup of materials and supplies in terminals, and for a distance of several miles out on the line, is now being handled largely by trucks where this work was formerly done by work trains. The use of tractors is becoming more general in the movement of heavy equipment and materials from point to point.

One railroad reports that the use of a caterpillar dragline has eliminated fifteen days' work-train service from a 45-day job.

With reference to other means of reducing work-train service, a railroad serving New York and the New England States reports a 30 per cent reduction during the past ten years through the use of motor trucks on concrete highways.

Another road reports that the regular supply train handles all work train duties set up for it.

A southwestern railroad reports that auto trucks, some with special equipment, have been found of great value and have been given extended use during the past ten years in connection with the maintenance of electric lines on streets, both on track and overhead. These trucks are used to move frogs, rail, ties, tie tamping and welding equipment, etc., the same as motor cars and trailers are used for this service on tracks not on streets.

Another road has found it possible, especially on light traffic lines, to lineup cars behind the caboose and cut them off on the main track, under flag protection, at the place where contents are to be unloaded. The empties are pushed into the clear by the next train. It was formerly the practice on this railroad to unload concrete, sand and

gravel by clamshell or by hand from gondola coal cars. They have followed the practice lately of loading the material in hopper cars and plowing it off in the track at the bridge site in a fraction of the time formerly taken. A slight excess of material is ordered.

One railroad reports the use of narrow-gage dump cars in cuts requiring constant ditching. Work train expense can sometimes be avoided by spotting cars on sidings and yard tracks, engine leads and other tracks until material is unloaded. The same road has found it practicable, in some places, to use caterpillar bulldozers in lieu of ditchers.

These substitute measures are being employed on work formerly requiring work train service.

Jobs handled by equipment of various kinds, resulting in reduction of work train expense are: Erecting signals, placing heavy riprap, picking up scrap with magnet attached to self-propelled cranes, and distributing station coal by truck from one central set-out point.

### Mowing, Discing and Burning Weeds

Mowing, discing and burning weeds by self-propelled machines are now extensively used in place of chemical spraying with work train.

### Oiling Roadbed

Oiling roadbed, to keep down dust, with self-propelled oiling machines are now used. This was formerly done by fastening spray to tank car moved by work train.

### Discussion

It is claimed that all of these operations described in the foregoing have resulted in saving money, reducing obstruction of main tracks, and effecting more prompt delivery of men and materials. Work train time is reduced and work is done at lower cost. A saving of materials is reported and in many instances a more workmanlike job is secured.

Concerning the further substitution for work train service now considered feasible, the consensus of replies indicates the more extensive use of off-track equipment, particularly motor trucks and caterpillar equipment.

Work-train service appears to be still essential where materials to be handled are of such quantity, weight or kind that there is no economy in attempting to handle them by any other means. Such materials are rail, ballast, ties where more economical to distribute than store on station grounds, cinders and refuse, telegraph poles, cast iron and concrete pipe, etc.

On large construction or rehabilitation jobs it may be more economical and practicable to move large camp outfits, derricks and pile drivers in work trains.

Ditching with steam shovel type or spreader type ditchers, eradicating weeds with chemical outfits, oiling roadbed with spray equipped tank cars, handling snow plows, large ballast cleaning machines, moving dirt in large quantities for grading sites for new construction and handling pile drivers at bridges a considerable distance from point of clearance are operations requiring work train service.

Emergencies such as washouts and fires and where quick clearance of trains is required, it is almost always considered necessary to have work-train service.

The necessity for much work train use results from local freight trains being taken off or in some territory running at night and the extreme difficulty of handling outfits in heavy tonnage trains, which in certain territory are often the only trains available. Ordinarily, operations such as those outlined that require work-train service, if there are

many men involved, can be performed more economically for the railroad if it is done by work-train service than to have men waiting to use revenue trains.

Where heavy material in any quantity is handled, it may be found possible to perform the work in such a way that work-train service of itself is not essential, but any substitute must have more or less the characteristics of a work train and may be equally expensive.

### Restriction of Movements of Equipment

The use of self-propelled equipment is restricted by statute in North Dakota, and, on the railroad making reply to this question, by agreement with employees to the extent that pilot conductor shall be employed when equipment which cannot be lifted on and off the track is used. The agreement with the employees is limited to the handling of standard cars with self-propelled cranes. For weed mowing machines, weed burners, etc., they operate on train orders without pilot conductors.

Self-propelled equipment is restricted by statute in Wisconsin to the extent that a full crew is required where self-propelled machines are used outside of terminals, regardless of whether or not a locomotive is used with them.

The use of self-propelled equipment is restricted in California by Assembly Bill No. 927, Chapter 501, and amendments approved May 25, 1915. On lines with more than four trains per 24 hours, self-propelled equipment covered by the Act must operate within one-half mile of a set-out track or be in charge of a train crew.

In Ohio, railroads are prohibited by statute from switching cars, that is, coupling or uncoupling a self-propelled crane. This applies whether working on the main line or on a siding. On this railroad, operating in Ohio, in most cases where self-propelled equipment is working on the main line, a full crew is required to protect the movement.

A road serving the southwest reports that the use of self-propelled equipment is restricted by statute only as to air brakes, couplers and other M.C.B. devices. Agreements with employee organizations provide that a qualified conductor shall be used as pilot in handling and using self-propelled equipment on running tracks.

Another railroad advises that, under their wage agreements, they are required to have a crew of not less than one conductor and two brakemen where necessary to work under train orders.

A southern road reports that pile drivers and locomotive cranes which cannot be readily removed from the track are provided with a crew when required to work more than one-half mile from a siding.

On a large eastern system, self-propelled equipment may be used on sidings and in yards with only maintenance personnel, but train crews are required when operating on main line.

On one large railroad, self-propelled equipment is restricted by the fact that train service employees must be given the opportunity to qualify on such equipment when used in the movement of cars in maintenance of way service. Movement over main running tracks must be protected by qualified train service employees and such equipment must be operated by qualified work equipment operators.

Three eastern railroads state that while they are not restricted by statute, it is necessary to use a full flagging crew when main tracks are occupied in order to provide protection.

Statutes and working agreements requiring train crews destroy savings that otherwise would be secured by the use of self-propelled equipment.

One railroad advises that the operation of self-propelled equipment between any two stations is permitted without the services of a conductor pilot or flagman. In such

cases employees in maintenance gangs perform necessary flagging under the rules. Where such equipment is moved beyond the territory lying between two stations immediately adjacent, a conductor pilot is required and in some instances, when desirable from the railroad's standpoint, in order to facilitate the movement of the equipment, a flagman from the train service is also assigned to the equipment.

When it is definitely determined that a work train or work-train crew is required, the general practice is for the Division Engineer to make a request upon the Division Superintendent, either direct or through the Chief Dispatcher. On some roads, however, approval must be issued by the Engineer Maintenance of Way or Chief Engineer before a work train is authorized.

### Conclusions

As a result of its study, the Committee has reached the following conclusions:

1. That maintenance of way operations should be carefully planned to reduce the number of work trains required.

(a) By so programming the work as to permit it to be done in consecutive order and eliminate duplicate movements.

(b) By utilizing spare time of light extra and local trains.

(c) By having a thorough understanding by all concerned in the transportation and maintenance departments regarding work to be done and time required to do it.

(d) By insuring that locomotives assigned have sufficient power to handle the work.

(e) By loading materials in suitable cars.

(f) By selection of the proper type of crane for unloading and loading rail and having a properly organized gang experienced in the kind of work being done.

(g) By lining up work to be done in consecutive order to avoid backup movements and having sufficient work for a full day's work-train service.

(h) By the extended use of motor cars to handle men and material.

(i) By the use of other self-propelled equipment wherever suitable.

(j) By further development and use of off-track equipment.

### Recommendation

Your Committee recommends this report be accepted as information and the subject discontinued.

### Appendix C

#### (5) PROGRAMMING OF BRIDGE AND BUILDING WORK

A. E. Botts, Chairman, Sub-Committee; W. R. Bennett, C. S. Colvin, J. F. Dobson, Paul Hamilton, H. E. Perkins, F. R. Rex, H. M. Righter, C. R. Wright.

1. Secure by careful field inspection, by competent representatives, first-hand information of the work to be performed and the material required. This inspection to include:

(a) All material required for the ensuing year.

(b) Lumber required for the second year, which will necessitate 12 months seasoning in advance of treatment, such as oak bridge ties.

2. Classify each of the projects, at time of field inspection, by one of the three following designations:

- (a) Additions to and Betterments of Existing Facilities  
(Work entailing charges to Capital Account)
- (b) Maintenance of Existing Facilities  
(Work of major importance)
- (c) Maintenance of Existing Facilities  
(Work of minor importance)

3. Assign an item number to each project for reference purposes.

4. Furnish Supply Department with forecast of materials required, separating as outlined under sections (a) and (b) of paragraph 1.

At this point it is necessary to separate the work into two groups:

#### *Maintenance of Existing Facilities*

#### *Additions to and Betterment of Existing Facilities*

- |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### RECOMMENDED FORMS

#### FORM NO. 1—INSPECTION FOR ANNUAL AND STRUCTURE PROGRAM

This form has been prepared for the recording of data obtained by the field inspection.

Each project requiring attention should be listed and a complete bill of material made.

Each project should be classified as "A", "B", or "C", as follows:

- Class "A" Improvements to Existing Facilities, Additions and Betterment work will require securing authority for capital expenditures.
- Class "B" Maintenance of Existing Facilities, Maintenance work of major importance.
- Class "C" Maintenance of Existing Facilities, Maintenance work of minor importance.

Upon completion of the field inspection, original of Form 1 should be forwarded the Chief Engineer or Engineer Maintenance of Way for preparation of annual budgets, copy to be retained by local officer.

Form No. 2 should be prepared by operating divisions as the information contained in the columns "Estimated Cost" and "Schedule of Work (Line E)" should be used in the preparation of annual forecasts of Maintenance of Way expenditures and for the setting up of monthly allowances.

The estimated cost of performing work on each project should be determined by the Chief Engineer or the Engineer Maintenance of Way, or secured from local officers, and inserted in column captioned "Estimated Cost". These estimated amounts should also be distributed to the various months in the columns captioned "Schedule of Work and Monthly Expenditure". The schedule estimate should be identified by using the letter "E".

Copy of Form No. 2 should be furnished the division maintenance officers to permit their ordering necessary materials and the scheduling of the work by forces.

In some cases it will be found desirable to have the costs of various classes of work on a single project kept separate. When this is desirable, an additional reference number may be assigned under "Code Reference".

#### FORM NO. 3—ANNUAL BRIDGE AND STRUCTURE FORCES PROGRAM

Division maintenance officers upon receipt of Form No. 2, "Annual Bridge and Structure Program", should prepare schedule of work to be performed by each force.

This schedule should be prepared on Form No. 3, "Annual Bridge and Structure Force Program" and should agree in detail with the projects as listed on Form No. 2, "Annual Bridge and Structure Program".

Division maintenance officers should furnish each foreman with copy of the schedule of work to be performed by his force, and should also arrange for the ordering of the material.

#### Progress Report

Semi-monthly or monthly Progress Reports can be used to a considerable advantage for the purpose of keeping Maintenance of Way officers posted on the status of work on each project.

This information can well be furnished in typed statement form by reporting the following:

|                 |                                    |
|-----------------|------------------------------------|
| Division        | Per cent scheduled for month       |
| Name of foreman | Per cent completed during month    |
| Item number     | Per cent scheduled to date         |
| Code number     | Per cent completed to date         |
| Location        | Date completed                     |
| Date started    | Remarks: (Reason for delays, etc.) |
| Man-hours       |                                    |

Progress as shown on this report should be posted to Form 2, "Annual Bridge and Structure Program", and to Form 3, "Annual Bridge and Structure Force Program," in the proper column (month) under "Schedule of Work and Monthly Expenditures", and should be identified by the letter "G".

#### Report of Expenditures

To permit complete record being maintained on Form No. 2, "Annual Bridge and Structure Program", and to Form 3, "Annual Bridge and Structure Force Program," a monthly statement of charges should be secured from the accounting records.

The form should include the following information:

|             |                      |
|-------------|----------------------|
| Division    | Location             |
| Item number | Labor expenditure    |
| Code number | Material expenditure |

Costs as shown on this report should be posted to Form No. 2, "Annual Bridge and Structure Program", and to Form 3, "Annual Bridge and Structure Force Program," in the proper column (month) under "Schedule of Work and Monthly Expenditure", and should be identified by the letter "F".

## Appendix D

## (6) REVISED PLANS FOR OUTFIT CARS FOR MAINTENANCE OF WAY DEPARTMENT EMPLOYEES

G. M. Magee, Chairman, Sub-Committee; William Elmer, H. I. Hoag, J. G. Wishart.

In his address before the Twentieth Annual Convention of the A.R.E.A., President C. A. Morse gave the following quotation from Frances A. Kellor, at that time Assistant to Chairman, Immigration Committee, Chamber of Commerce of the United States:

"Where do we find ourselves today in handling labor? All the way from the ditched box-car, vermin-ridden and disease-laden, housing workmen neglected and isolated, at one end of the scale, to the Ford plant at the other."

With reference to the above quotation, the President commented:

"We have made some advances during the past two or three years toward improving the situation on the railroads. We must go at it on a much larger scale, not from a humanitarian point of view but from a business point of view."

In the Proceedings for this same year, Committee XXII reported on "Typical Plans for Housing Labor". This report contained typical plans for the construction of camp or outfit cars and these plans were very beneficial in bringing about an improvement in the sanitation and comfort of outfit cars for floating gangs.

Since 1919 railways have shown a continued interest in improving the living conditions of outfit cars. In recent years this subject has increased in importance due to the tendency towards increasing use in railway maintenance work of specialized gangs equipped with labor-saving equipment and employing in many instances men accustomed to higher standards of living. On some roads where the standard of living to which the men were accustomed have justified it, outfit cars have been provided from retired passenger equipment and very completely equipped with comfortable beds, running water, lavatories, shower baths, sanitary toilets, electric lights, recreation rooms, refrigeration and generally improved living conditions.

Revision of the earlier plans for outfit cars was assigned to this Committee. This Committee requested standard plans of outfit cars from a number of roads and these plans were kindly furnished. After careful study, the following plans have been prepared to represent the most satisfactory general arrangement and equipment of outfit cars for maintenance of way work. It is realized that in almost every condition some special consideration must be given to most efficiently meet the individual problems. For that reason, these plans have been prepared for general use in such a manner that suitable revisions may be easily made to suit the required standard of living, size of gang, type of work, or other specific considerations.

Reference is made to Railway Engineering and Maintenance, page 248, 1929, for photographs of these camps.

The following points should be considered by the individual road in the design of outfit cars:

(1) The standard of living conditions provided in outfit cars should be consistent with that to which the occupants are accustomed so the occupants will enjoy their quarters on the one hand and the quarters will not be subject to abuse by the occupants on the other.

(2) More comfortable living conditions may justifiably be provided for the gangs employed continually the year round than for gangs employed in seasonal work.

(3) The cars should be well constructed and properly insulated for economy in heating and comfort in both winter and summer.

(4) Platform type steps at the ends of the cars are desirable both as a matter of convenience and safety.

(5) The interior finish and painting should facilitate cleaning and sanitation.

(6) Good ventilation and comfortable beds in sleeping rooms will materially improve the day's work.

(7) Sanitation and convenience in the kitchen and dining room should be of major consideration.

(8) Electric lights, running water, toilet facilities and adequate heating will aid materially in retaining desirable men in service.

(9) Proper refrigeration should be provided to prevent loss of foodstuffs and to safeguard health.

(10) Cars selected for use as outfit cars should have underframes and superstructure of sufficient strength to enable them to be handled any place in train without danger of buckling.

### Conclusions

The accompanying drawings show typical plans for the construction and arrangement of:

Foreman car  
Kitchen and dining car  
Recreation car

Sleeping car  
Water and fuel car

for use in the maintenance of way, using either freight or passenger equipment. Your Committee recommends that living conditions of outfit cars be made as comfortable and sanitary in accordance with these general plans as economic considerations permit.

### Appendix E

#### (8) GANG ORGANIZATION AND METHODS OF PERFORMING MAINTENANCE-OF-WAY WORK, INCLUDING REVISION OF TIME STUDIES NOW IN THE MANUAL

C. H. R. Howe, Chairman, Sub-Committee; Paul Hamilton, H. I. Hoag, C. A. Johnston, G. M. Magee, J. A. Parant, H. M. Righter.

The Committee has continued its investigation of the time studies now remaining in the Manual with view of revising such of them as are not representative of modern practices.

Considerable information has been secured on the subject of mechanical tie tamping organizations, but there are now in process of development certain innovations in the design of equipment used on this class of work that should prove to be of value. As soon as it is practical to do so, this information will be embodied in a report for the consideration of the Association.

#### Recommendation

It is recommended that the subject be continued.

*Committee.*

*To the American Railway Engineering Association:*

Your Committee respectfully presents herewith its report on the following subjects:

- (1) Revision of Manual.
- (2) Specifications for prepared gravel ballast, including best method of testing for hardness, abrasion and resistance to weathering (Appendix A).
- (3) Specifications for stone ballast, including best method of testing resistance to weathering (Appendix B).
- (4) Comparative costs of maintaining track on various kinds of ballast (Appendix C).
- (5) Effects of different kinds of ballast on life of ties, on life of rail and upon rail failures, particularly as between gravel and crushed stone ballast. Committee reports progress.
- (6) Determine proper depth and kind of sub-ballast (Appendix D).
- (7) Effect of better and deeper ballast on the cost of lining and surfacing. Committee reports progress.

### Action Recommended

- (1) Changes are covered in Appendix D.
- (2) That Appendix A be accepted as a progress report.
- (3) That Appendix B be accepted as a progress report.
- (4) That Appendix C be accepted as a progress report.
- (6) That the recommended revisions of the Manual appearing in Appendix D be approved.

Respectfully submitted,

THE COMMITTEE ON BALLAST,

A. P. CROSLY, *Chairman*.

### Appendix A

#### (2) SPECIFICATIONS FOR PREPARED GRAVEL BALLAST, INCLUDING BEST METHOD OF TESTING FOR HARDNESS, ABRASION, AND RESISTANCE TO WEATHERING

C. B. Stanton, Chairman, Sub-Committee; W. L. Foster, J. J. Gallagher, O. N. Lackey, W. A. Roderick, Stanton Walker, A. O. Wolff, A. H. Woerner.

The Committee is not able at this time to present information in addition to that given in its last year's report. This does not mean, in any sense, that the assignments to the Committee have been completed, but only that conditions during the past year have not been conducive to carrying forward the work.

In addition to its studies of a suitable grading for ballast, the Sub-Committee, during the past three years, has concentrated the largest proportion of its efforts on the development of information on methods of testing for hardness, abrasion, and resistance to weathering. In connection with these studies, 21 samples of gravel ballast were collected through the cooperation of railroads and of gravel producers, and subjected to abrasion, crushing, specific gravity, absorption, grading, weight, void, and soundness tests (see Vol. 31, 1930, page 761, and Vol. 33, 1932, page 350, of the Proceedings). Information concerning the service record in the track of 18 of these samples has been furnished to the Committee by representatives of the railroads (see Vol. 34, 1933, page 524, of the Proceedings).

These data have not shown sufficient correlation between the results of the field observations and the laboratory tests to indicate clearly what specification limitations should be placed on the various physical characteristics of gravel ballast, although some promising results were obtained. The Committee feels that the investigation should be continued along similar lines, with special attention being paid to the collection of samples representing a wider range in quality than those which have already been tested.

In addition to the tests on physical characteristics, the Committee has endeavored also to develop some information on the effect of grading and the proportion of crushed particles on the stability of gravel ballast in the track. So far this work has consisted only of some preliminary laboratory investigations of test methods. It cannot be said that the results obtained to date have been particularly valuable, but it is believed that this represents a problem which deserves further attention.

The Committee recommends, therefore, that these assignments be continued and it also asks the indulgence of the Association in making somewhat slow progress until economic conditions permit a more vigorous prosecution of the work.

Report is submitted as information.

### Appendix B

#### (3) SPECIFICATIONS FOR STONE BALLAST, INCLUDING BEST METHOD OF TESTING RESISTANCE TO WEATHERING

J. M. Podmore, Chairman, Sub-Committee; C. J. Coon, H. F. Fifield, W. L. Foster, A. T. Goldbeck, W. W. Patchell, H. M. Richter, A. B. Shimer.

At the 1933 convention, your Committee submitted as information an alternate method for making an abrasion test on crushed stone as produced for ballast, known as the Modified Abrasion Test. Before recommending the adoption of this test it seems desirable to await developments from a series of tests which largely have been completed on still another modified form of abrasion test, making use of the so-called Los Angeles

Rattler. Perhaps, also, a series of cooperative abrasion tests should be conducted to determine the proper test values to use in specifications for ballast. Your Committee recommends that tests for abrasion be given further study and, at a later date, that cooperative tests be undertaken to secure an idea of the proper test limits to be used in specifications for ballast.

Your Committee recommended that the section dealing with cementing value be removed from the specification for ballast. However, by instructions from the convention the subject of cementing value has been given further study. During the past year a questionnaire was sent out to railroads. Answers were received from 58 railroads, six of which advised that the cementing value test is used in the purchase of stone ballast. Of these six, five specify the A.R.E.A. method of making the test and one specifies a method which differs in a few details from the A.R.E.A. method. The answers to these questionnaires appear in the tabulation attached to this report.

The test requirement specified by the six railroads using the cementing value test varies all the way from 1 lb. to 450 lb. per sq. in. Tests made in the laboratory of the National Crushed Stone Association have shown that the cementing value of excellent trap rock may be as high as 670 lb. per sq. in. and of an excellent grade of limestone as high as 670 lb. per sq. in. Crushed quartz sand was shown to have a cementing value of 32 lb. per sq. in. when the test was conducted as required by the A.R.E.A. specification. A tabulation of test results for cementing value obtained in the National Crushed Stone Association laboratory is included herewith (See Table No. I).

Obviously, in view of the wide variation in the specification requirements of the six railroads using the cementing value test, coupled with the high results obtained with the A.R.E.A. test method, it is evident that an inconsistency exists, either in the test method itself, or in the requirements of the railroads specifying the A.R.E.A. method. Because of this inconsistency, it seems desirable to initiate a cooperative series of tests which will shed light on this entire matter of cementing value of rock for use as railroad ballast.

Such an investigation would seem to involve:

- (1) A determination of the duplicability of the test method when made in different laboratories.
- (2) A determination of the value of the test method for revealing the cementing value of rock under actual service conditions.

Do high cementing value laboratory test results consistently prove that the rock has highly cementitious properties in service? Do low results indicate a rock of excellent properties from the cementation standpoint as revealed by service results?

Perhaps through a cooperative series of tests some real facts will be obtained with regard to the test for cementing value. Your Committee is of the opinion that a cementing value requirement is unnecessary in connection with hard and tough rocks such as trap and granite, for very little dust is formed due to abrasion of these stones in actual service. On the other hand, soft grades of limestone which break down under the action of tamping tools and traffic and which are lacking in durability upon exposure to the weather, may form a large amount of dust. This dust when combined with water may produce a plastic mud which would stick together and interfere with drainage. It would seem that if the cementing value test has merit, its principal value must be in connection with these soft, non-resistant materials.

Your Committee is taking steps to initiate a cooperative series of cementing value tests with objectives as already indicated, with the hope of obtaining information of practical value for use in specifications for ballast.

### Recommendation

That the above report be received as information.

**TABLE I**  
**TABULATION OF THE RESULTS OF TESTS ON RAILROAD BALLAST**  
 For the Committee on Ballast, A.R.E.A. Made by the National Crushed Stone Association, January 1931

| Lab. No. | Material        | Spec. Grav-ity | Absorp-tion % | Per cent Wear (Deval) | Coef. Hard-ness (Dorry) | Tough-ness (Page) | Crushing Strength lb./sq. in. | Cement-ing Value lb./sq. in. ## Appendix C

### (4) COMPARATIVE COST OF MAINTAINING TRACK ON VARIOUS KINDS OF BALLAST

J. B. Wilson, Chairman, Sub-Committee; J. J. Gallagher, C. G. Grove, Daniel Hubbard, H. M. Long, C. S. Wicker.

During the past year your Committee has endeavored to obtain information on this subject, with very little success. Ballast on one of the two sections reported on for the past few years has been changed; therefore these sections have been eliminated from further comparative study.

The following is a brief outline of the information desirable for a report on this subject:

(A) TRACK—

1. Weight of rail
2. Joint
3. Per cent of and size of tie plate
4. Size and spacing of ties
5. Kind of ties and per cent treated

(B) BALLAST—

1. Kind
2. Specifications
3. Depth and material of sub-ballast
4. Depth of top ballast
5. Ballast section
6. Cost per yard delivered to railroad

(C) ROADBED—

1. Character of subgrade
2. Alinement

(D) TRAFFIC—

1. Number per day and average speed of passenger trains
2. Number per day and average speed of freight trains
3. Type of locomotive
4. Tonnage

(E) LABOR—

1. Size and makeup of gangs
2. Man hours separated between foremen, laborers, etc.

(F) MAINTENANCE METHODS—

1. Cycle of maintenance
2. Kind and number of mechanical appliances used

(G) COSTS—

1. Detail costs per mile of track reported on.

## Conclusion

The Committee believes that no accurate comparison can be obtained from data such as is being kept by railroads. Only by test sections carefully watched by this Committee for a period of several years can definite conclusive results be obtained.

## Appendix D

## (6) DETERMINE PROPER DEPTH AND KIND OF SUB-BALLAST

A. D. Kennedy, Chairman, Sub-Committee; C. G. Grove, O. N. Lackey, J. M. Podmore, C. P. Richardson, J. W. Stone, A. H. Woerner.

This question was first assigned in 1931. It involves the old question of "Proper Depth of Ballast" which has been before the Association since 1902. To familiarize itself with this subject, the Committee made a survey of the Proceedings of the Association, and offers for convenience, the following historical review:

The first mention of the question of "Proper Depth of Ballast" is in Vol. 3, page 130. The Committee made this recommendation: "For ballast materials that will stand at a one-to-one slope, such as crushed stone, not less than the distance between the ties; for other materials that will stand at a lesser slope requires a greater depth."

On page 104, Vol. 7, Mr. Johnson states a formula for proper depth of gravel and stone ballast. This formula is largely based on the findings of Director Schubert of the German Railways from a lecture delivered in Berlin in 1899. A translation is given on page 105.

In Vol. 12, Part 1, page 341, are given some of the conditions on which depend the "Proper Depth of Ballast," and in Appendix A, page 345, is given the depth of various kinds of ballast used at that time by representative railroads.

On pages 95 to 265 inclusive of Vol. 13 is given interesting information regarding this subject, particularly regarding experiments and tests conducted by the Pennsylvania Railroad. These experiments and tests were made with new or clean ballast and not under regular traffic conditions.

With the data made available by these tests, the Ballast Committee of that year concludes as follows: "Your Committee finds that with the ties ( $7'' \times 9'' \times 8\frac{1}{2}'$ ) spaced approximately 24 in. to 25.5 in. center to center, a depth of 24 in. of stone ballast is necessary to produce uniform pressure on the subgrade, and a combination of a lower layer of gravel or cinder ballast (18 in. to 14 in.) and an upper layer of stone ballast (6 in. to 10 in.) approximately 24 in. in depth in the aggregate with the same spacing of ties will produce nearly the same results."

The question of "The proper depth of ballast of various kinds to insure uniform distribution of loads on the roadway" is summarized in the Committee's report in Vol. 16, pages 1011 to 1015. In this summary, reference is made to a proposed test to be conducted under regular traffic and under the supervision of the Committee. In the discussion on the report of this Committee, skepticism was expressed relative to any recommendation which makes 24 in. the proper depth of ballast, the inference being that sufficient information on which to base or support a recommendation was not available.

In Vol. 17, the same question was considered under the caption of "The economical and efficient depth of ballast." The Committee recommended in their report the carrying out of the special test suggested in previous reports. (A complete outline of this test is given on page 1015, Vol. 16.) In Vol. 18, the Committee submitted, for information, that the proposed test would be installed in 1918. However, subsequent reports do not indicate this test was ever carried out.

Under discussions on report of the Committee on Stresses in Railroad Track on page 1476, Vol. 18, it was stated that laboratory tests showed that the pressures begin to become rather uniform when a depth of 18 in. or 20 in. under the tie is reached.

On page 454, Vol. 18, attention is directed to the fact that the recommended depth of ballast of 24 in. was made on the assumption of 2640 ties per mile, and that at this

time railroads were increasing the number of ties per mile, which would affect the recommended depth of ballast.

At the 1917 convention, the proper depth of ballast was adopted, viz., "The depth of ballast under the tie on roadbed materials, such as clay, loam, etc., subject to deformation by the application of live loads, would seem to be not less than the spacing of center to center of ties."

In Vol. 22, page 80, Appendix A, the recommendations of the preceding committees on proper depth of ballast is carried up-to-date and summarized into six paragraphs. This summary was approved and now appears in the 1929 Manual on page 102, and for convenience, these paragraphs are quoted, as follows:

#### "PROPER DEPTH OF BALLAST

"(1) On a roadbed material such as clay, loam, etc., subject to deformation by the application of live load, the proper depth of ballast under the tie to produce approximately uniform pressure on the roadbed, should be not less than the spacing center to center of the ties. For Class A Track, see Ballast Sections.

"(2) On material that approximates the character of good sub-ballast (which will not be deformed by the application of live load), the minimum depth of ballast under the bottom of the tie should be twelve (12) in.

"(3) These depths are required, under the conditions named, to support the track structure; to provide good initial drainage; to reduce upheaval by frost; to serve as a cushion for the track.

"(4) A combination of a good sub-ballast 18 to 14 in. and top-ballast 6 to 10 in., making a total of approximately 24 in. under the tie in the aggregate, will produce nearly the same result as though the superior material was used for the full depth.

"(5) Until sufficient tests are made under normal traffic conditions, the proper depth of ballast under the tie must rest on opinion, based on experience and supported by such tests as are available, notably the test made by Director Schubert of the German Railways and the 'Altoona Test' made by the Pennsylvania Railroad.

"(6) Proper drainage of the subgrade is essential to success with any kind of ballast."

In considering this new subject of "Proper depth" and kind of sub-ballast, a distinction should be made between new construction and old established lines.

In new construction, such materials as screenings, pit run gravel, cinders, slag, sand, etc., are used as sub-ballast with satisfactory results, but, in general, availability and cost determine the kind to use. It is not considered good practice to place a ballast section of materials such as crushed stone, broken slag or prepared gravel on new subgrade, without sub-ballast, since the subgrade materials (consideration to be given to the materials in the subgrade) will, under traffic, become mixed with the ballast.

After years of service, the sub-ballast of an original ballast section loses its identity as such. It becomes so mixed with the subgrade that a distinction is impossible and with repeated replenishments of the top-ballast section, several feet of top-ballast material have been found under the ties. Therefore, the Committee concludes the question of sub-ballast does not apply to old, established roadbeds but is restricted to new construction.

The Committee is of the opinion that within certain limits materials of smaller aggregates are to be preferred for sub-ballast, since such materials have a greater tendency to prevent the subgrade working up into the ballast. The thickness or proper depth of sub-ballast to use depends upon sundry conditions and variables. Experienced engineers, after acquainting themselves with all the conditions to be encountered, should be able to approximate the proper depth to use.

Some railroads, in their reply to the questionnaire (details of which are given in Appendix E of the 1932 report), indicated that due to the increased weight of power,

equipment and changes in general conditions, the 24-in. ballast section, as shown in the 1929 Manual, is not adequate for their present-day needs. For this reason and for lack of definite information regarding the many existing and ever-changing conditions particular to each location, your Committee feels this Association cannot defend, except by opinion, a ballast section of any specific dimensions. However, there is information contained in the Proceedings of the Association, reference to which is given in this report, which, if intelligently interpreted, would be a guide in determining both the proper depth of ballast and sub-ballast to use in any particular location.

The Committee feels that paragraph five (5) under the caption "Proper Depth of Ballast," as it now appears in the Manual, conflicts with the preceding paragraphs. We further find the minimum ballast sections of 12 in. and 24 in., approved by the Association, are not supported by data. Therefore, your Committee recommends the following be substituted for the six paragraphs, under the caption "Proper Depth of Ballast."

(1) There is a relationship between several conditions, viz., rail section, ties, tie spacing, kind of ballast, speed, wheel loads, drainage, subsoil, kind of traffic, etc., and the depth of ballast. Depth of ballast should exceed the minimum required to uniformly distribute superimposed loads to the subgrade without causing its deformation. Available data does not support a definite specification with reference to required depth for general application under all conditions.

(2) In new construction a combination of good sub-ballast and top-ballast does, with few exceptions, produce better results than a superior material used for the full depth. The ratio of the one to the other and the total depth in the aggregate should be determined with due consideration given to local conditions, as outlined in Paragraph 1.

NOTE.—In the absence of more specific data, the tests made by Director Schubert of the German Railways (Vol. 7, pages 104 to 127) and by the Pennsylvania Railroad (Vol. 13, pages 95 to 265), although not conducted under regular traffic conditions, are of great value as a guide in determining the depth of ballast required for any given section of track.

Reference is also made to Vol. 12, Part 1. On page 341 are given some of the conditions on which depend the proper depth of ballast and in Appendix A, page 345, is given the depth of ballast used at that time by representative railroads.

It would appear from the present captions that the ballast sections shown on pages 103 and 104 of the Manual are the Association's recommended sections and do not admit of any modifications. The Committee recommends that these captions be changed to read:

TYPICAL STONE BALLAST SECTION WITH PARTICULAR REFERENCE TO SUB AND TOP-BALLAST  
(See under heading "Proper Depth of Ballast").

Similarly, the caption on page 105 to read:

TYPICAL GRAVEL BALLAST SECTION WITH PARTICULAR REFERENCE TO SUB AND TOP-BALLAST  
(See under heading "Proper Depth of Ballast")

On page 106 of the 1929 Manual are shown recommended ballast sections for Class "B" and "C" tracks which were adopted in 1907. The Committee recognizes that Class "B" and "C" tracks, under certain conditions, require ballast section equivalent to Class "A" tracks, and for this reason recommends striking out reference to Track "B" and "C" on page 106 and to change the caption on top of page to read as follows: "The sections shown below are suggested for less important main lines and for branch lines and other tracks of sundry importance (see under heading "Proper Depth of Ballast")."

### Action Recommended

That changes in 1929 Manual be approved as given above.

## REPORT OF COMMITTEE XVI—ECONOMICS OF RAILWAY LOCATION

W. D. WIGGINS,  
J. C. WRENSHALL,  
*Committee.*

*To the American Railway Engineering Association:*

### DEFINITION OF "RISE-AND-FALL"

The term "Rise-and-Fall" has been defined or used by various writers on the economic theory of railway location, and is frequently used by many engineers with or without explanation or definition. The following definitions have been abstracted from publications generally referred to in studies of railway location:

WELLINGTON—"Economic Theory of Railway Location," Par. 450.

"A foot of 'Rise-and-Fall' means a foot of ascent with its corresponding foot of descent."

RAYMOND—"Elements of Railroad Engineering," page 239.

"'Rise-and-Fall' is considered to be the rise in feet on an ascending grade and the corresponding feet of fall on some descending grade."

WEBB—"Economics of Railroad Construction," page 287, Par. 184.

"In the simplest case a 'Rise-and-Fall' of so many feet means a rise from the starting point to a summit and a return to the same level."

WILLARD BEAHAN—"Field Practice of Railway Location," page 175.

"It follows that the total 'Rise-and-Fall' of a line will be the difference in elevation of the extremities of the line plus the unnecessary summits and unnecessary drops. If ground is found to support a grade line all the way, the 'Rise-and-Fall' is merely the difference in elevations of the terminals of the lines."

WILLIAMS—"Design of Railway Location," page 219 and 255.

"The second class of grades, or those less than the ruling grade, are termed 'Rise-and-Fall'."

"'Rise and Fall' may be defined as the rise from a datum elevation to a summit with the corresponding descent to the same datum elevation."

1929 A.R.E.A. MANUAL—PAGE 1258—"('3') 'Rise-and-Fall'."

"'Rise-and-Fall' affect line resistance and may affect time, but to what measurable extent is indeterminate."

"The amount of 'Rise-and-Fall' of each alternate location in vertical feet should generally be determined and considered as an aid to judgment in forming final decision as between locations, but may be neglected entirely in comparing alternate locations where there is small difference in 'Rise-and-Fall'."

A study of these definitions reveals that different values may be obtained for the amount of "Rise-and-Fall". Where the termini of the section of road for which "Rise-and-Fall" is to be determined are at the same elevation, no confusion arises in computing it, the answer being the summation of vertical rises in the profile, as it is evident that

for each foot of rise there will be a corresponding foot of fall. Where there is a difference of elevation between the termini of the section of line under consideration, confusion arises in the determination of the number of feet of "Rise-and-Fall", as it is evident that there will be a difference between the sum of the vertical rises and the sum of the vertical falls by the difference in elevation between the termini.

As traffic in practically all cases moves in both directions over the same grades, it seems sufficient for all practical purposes to compute "Rise-and-Fall" for a round trip over the section under consideration. Under this method the total rises and total falls become equal, and the "Rise-and-Fall" for the line is given by one half the sum of the vertical ascents for a round trip. While the amount of "Rise-and-Fall" obtained from the computation of same for a round trip does not exactly fit the theory under which the effect of "Rise-and-Fall" on operating expenses is treated, no great error is incurred, and as the effect of "Rise-and-Fall" on operating costs is of minor importance the errors inherent in this method will be of little consequence.

In view of the above the Committee therefore presents the following definition of "Rise-and-Fall": "Rise-and-Fall" is the sum of vertical ascents in rising from a starting point or level to a summit and returning to same point or level, inclusive of all grades on the profile between any two points or termini. It is mathematically expressed by the formula

$$\frac{\text{Sum of ascents in one direction} + \text{Sum of descents in same direction}}{2}$$

#### EFFECT OF "RISE-AND-FALL"

While the mathematical definition of "Rise-and-Fall" given above may be used to obtain a mental comparison of two profiles, the figures thus obtained cannot be used in a concrete way for estimating the relative operating expenses of the two profiles. "Rise-and-Fall" to be useful for this purpose must be divided into the following classes, each of which has a different effect on operating expenses:

Class "A"—"Rise-and-Fall" in minor gradients and for small undulations, not sufficient to make it necessary to vary the power of the engine, but merely causing a momentary, gradual and unobjectionable fluctuation in speed. Not requiring shutting off steam, nor change in the natural velocity, nor use of brake or sand.

Class "B"—"Rise-and-Fall" similar to Class "A", in its effect on speed, provided steam be shut off in descending, but not requiring the use of brakes in descending, nor seriously taxing the power of the engine on the ascent. Requiring the shutting off steam at the head of the grade but not use of brakes or sand.

Class "C"—"Rise-and-Fall" requiring the use of brakes in descending, in addition to shutting off steam, in order to avoid excessive velocities and consequently in almost all cases, more or less use of sand in ascending. Requiring use of both brakes and sand.

Separation of "Rise-and-Fall" as among the three classes given above is accomplished by first fixing the maximum permissible speed for the class of service under consideration, and second, by the construction of a virtual profile by the usual method, on which the grades of each class can be marked in colors.

Preparation of the virtual profile and determination of "Rise-and-Fall" according to the above classifications requires a study of the actual profile and alignment and other features of the line, including locations where for any reason the speed of trains must be restricted, and of the characteristics of the locomotive used.

In any computation of costs Class "A" can be omitted, no expense can be directly traced to it in any single item. This leaves Class "B" and Class "C" to be considered in the determination of operating cost. For these classes no leading item of operating expenses is largely affected and very many are not affected at all.

"Rise-and-Fall" is most conveniently estimated in terms of vertical feet. The use of the number of vertical feet without any qualifications as an aid to judge between two locations may mean practically nothing.

Fig. 1 and 2 show two profiles which have the same "Rise-and-Fall". However, the grade is much heavier in one case than in the other, and to assume equality in cost of operation over them because of the fact that "Rise-and-Fall" is the same in each case is erroneous.

Fig. 1.

$$\text{Rise and Fall} = 90 = Cc = \frac{\text{Rise in AC} + \text{Fall in BC}}{2}$$

Fig. 2.

$$\text{Rise and Fall} = \frac{\text{Rise AC} + \text{Fall CD} + \text{Rise DE} + \text{Fall EB}}{2} = \frac{50+20+40+70}{2} = 90$$

Fig. 3 further illustrates this. The two lines have the same "Rise-and-Fall", the ruling grade shown by solid lines is 1 per cent and the ruling grade shown by dotted lines is 1.5 per cent. A comparison of the operating cost over these profiles would have to be made on some other basis than "Rise-and-Fall", and it is possible the heavier ruling grade might be selected on account of various other factors.

Fig. 3.

In Fig. 3 are shown 2 profiles from A to B, one by Solid Lines, one by Dotted Lines. By adding together the rises and descents and dividing the result by 2 it will be found that Rise and Fall is the same on both profiles.

The maximum or operating grade on Dotted Line is 50% in excess of maximum grade on Solid Line, or

$$\text{R. \& F. (Solid Line)} = \frac{AC + CD + DE + EF + FG + GH + HI + IB}{2} = 550$$

## ITEMS OF OPERATING COST AFFECTED BY "RISE-AND-FALL"

The main effect of "Rise-and-Fall" is in fuel and time. At the present time the Committee is not prepared to offer any method of determination of the effect of "Rise-and-Fall" on these items of operating expenses or to state whether or not other items of operating expenses are affected by same, and to what extent.

## Conclusion

It is recommended that the following definition of "Rise-and-Fall" be adopted: "Rise-and-Fall" is the sum of vertical ascents in rising from a starting point or level to a summit and returning to same point or level, inclusive of all grades on the profile between any two points or termini. It is mathematically expressed by the formula—

$$\frac{\text{Sum of ascents in one direction} + \text{Sum of descents in same direction}}{2}$$

Respectfully submitted,

THE COMMITTEE ON ECONOMICS OF RAILWAY LOCATION,

F. R. LAYNG, *Chairman.*

*Committee.*

*To the American Railway Engineering Association:*

Your Committee on Rivers and Harbors respectfully presents its report on the following subjects:

- (1) Revision of Manual (Appendix A).
- (2) Definitions of Terms (Appendix B). These definitions are tentative and the Committee will welcome suggestions.
- (4) Specifications for the Construction of the Several Types of River Bank Protection in Common Use (Appendix C).
- (5) Types of Bulkheads, Jetties and Sea Walls, Giving Cross-Section of Each and Stating the Purpose which they Serve, Including Comparisons of First Cost, Service Life and Maintenance Cost of the Various Types (Appendix D).
- (6) Types of Fender Systems for Protecting Wharves and Recommend Suitable Uses for Each, Including Comparisons of First Cost, Service Life and Maintenance Cost of the Various Types (Appendix E).
- (7) Warehouse Piers, Coal and Ore Piers, Car Float Piers and Others, with Recommendation as to the Type Suitable for Use Under Various Conditions, Including Comparisons of First Cost, Service Life and Maintenance Cost of the Various Types (Appendix F).
- (10) Economic Principles Involved in Clearances over Navigable Waterways (Appendix G).
- (11) Cost to Railways for Construction, Maintenance and Operation of Bridges over Navigable Waterways: (a) In the Natural Condition of Streams; (b) Additional Costs brought about on account of the Enlargement of the Capacity of the Streams over and above their Natural Conditions (Appendix H).

It is the recommendation of your Committee that all the above reports be accepted as information and the subjects continued.

Progress is reported on the following subjects:

- (3) Suitable Types of Construction for Levees, Dikes and Mattresses for Use under Varying Service Conditions, giving Consideration to Stream Alinement, Subsurface, Soil or other Local Conditions.
- (8) Size and Depth of Slips Required for Economical Operation of the Various Types of Wharves and Traffic Conditions, including Comparisons of First Cost, Service Life and Maintenance Cost of the Various Types.
- (9) Harbor Structures.

Respectfully submitted,

THE COMMITTEE ON RIVERS AND HARBORS,

W. C. SWARTOUT, *Chairman*.

## Appendix A

## (1) REVISION OF MANUAL

E. H. Roth, Chairman, Sub-Committee; Robert H. Ford, W. C. Swartout, A. P. Wenzell.

Sub-Committee No. 1—Revision of Manual, after due consideration of the other Sub-Committee reports, has no recommendation to make on Manual revision for the current year.

The Committee is reviewing the Manual and Supplements thereto studying material therein which has heretofore been submitted by other committees, but which would now properly come within the scope of this Committee.

If any revisions are thought necessary on completion of this study, suitable recommendations will be submitted at a future date.

## Appendix B

## (2) DEFINITIONS OF TERMS (TENTATIVE)

W. C. Swartout, Chairman, Sub-Committee; W. J. Backes, L. R. Boettcher, D. J. Brumley, W. E. Hawley, G. A. Knapp, F. E. Morrow.

**BARGE.**—A low, light draft cargo boat usually flat decked and flat bottomed, generally used for conveyance of freight on inland and coastal waterways.

— **SELF-PROPELLED.**—A barge which may proceed under its own power.

**BOAT.**—Any water craft with a hollow hull.

**BULKHEAD.**—(1) A partition in a boat.

(2) A structure built to hold filling along a water front.

**CANAL.**—An artificial waterway.

— **BOAT.**—A boat built for conveyance of cargo on navigable canals.

**CLEARANCE, HORIZONTAL OR LATERAL.**—(1) The clear width between channel lines available for operation of boats.

(2) The clear width between bridge abutments and/or piers or the clear width between other structures in or adjacent to a channel.

— **VERTICAL.**—The clear height from a surface of the water to the lowest point of a structure over a waterway.

**CRAFT.**—Any floating transportation unit.

**DRAFT (OF BOATS).**—The depth to which a craft sinks in the water.

**DAM.**—A barrier across a waterway to impound water.

**ECONOMIC JUSTIFICATION.**—The requirement that the earnings from a project under competent and careful management shall be sufficient to pay annually, after a predetermined development period, the interest on the total amount invested including development costs, depreciation on the entire plant, an amount equal to all taxes legally assessable, and all other costs or charges accrued necessary to maintain the project in proper condition for efficient operation.

**LOCK.**—A structure in a waterway for the purpose of raising or lowering water craft to predetermined elevations by opening and closing control gates.

**NAVIGABLE.**—Capable of being navigated by water craft.

— **WATERWAYS, NATURAL.**—A natural stream or channel of sufficient width and depth for practical navigation by water craft without dredging or construction of controlling works.

— **ARTIFICIAL.**—A stream, channel or canal made navigable by dredging and/or construction of controlling works.

**NAVIGATE.**—To sail over, traverse by water craft.

**NAVIGATION.**—The art of navigating.

**PASSING BASIN.**—A widened portion of a river or canal to permit water craft to pass one another.

**PIER, PRIVATE.**—A pier or dock owned or restricted to use by one or more individuals or corporations.

- **PUBLIC.**—A pier or dock operated for the benefit and use of the public.
- PILES, ANCHOR.**—Piles driven on the land side of a bulkhead or pier to which the bulkhead or pier is anchored or tied by rods, cables, chains or other devices.
- **CLUSTER OR FENDER.**—Two or more piles driven and lashed together at the top for the purpose of controlling the position of water craft at bridges and piers.
- RIGHT-OF-WAY.**—An easement or right to use, for a specific purpose, land of another and founded on grant by writing or prescription.
- RIVER BOAT.**—Any water craft primarily designed to operate upon inland streams and/or canals, or any similar water craft principally so used.
- SHIP (Noun).**—A vessel primarily designed for deep water navigation.
- TARIFF, FREIGHT.**—A published list or schedule of charges prescribed by lawful authority and applied under conditions stated therein for specified services rendered in the transportation of freight.
- TOLLS, WATERWAY.**—A charge or compensation levied by law for the right or privilege granted in the use of specified inland and/or coastal waterways.
- TOW, PULL (Noun).**—Water craft being navigated by power other than its or their own, the tow line between the power unit and the tow being in tension.
- **PUSH (Noun).**—Water craft being navigated by power other than its or their own, the power unit operating behind the tow.
- TUG (Noun).**—A powered non-cargo carrying boat used to tow or handle other water craft.
- VESSEL.**—A boat designed to navigate the high seas or lakes.

## Appendix C

### (4) SPECIFICATIONS FOR THE CONSTRUCTION OF THE SEVERAL TYPES OF RIVER BANK PROTECTION IN COMMON USE

P. J. McCarthy, Chairman, Sub-Committee; G. J. Bell, L. R. Boettcher, A. F. Crowder.

#### DETAILED SPECIFICATIONS

##### 1. Location.—

2. **Work to be Done.**—The work to be done under these specifications consists of furnishing all material, labor, plant equipment, machinery and tools, and therewith constructing, erecting and installing about (...) linear feet of pile diversion dike and a (...) foot bankhead and revetment, as hereinafter specifically set forth.

(b) The right is reserved to vary the length of the diversion dike by either increasing or decreasing the length herein proposed, and the cost to the Railway Company shall be for a completed dike at the price bid by the Contractor per linear foot, plus a lump sum to cover the (...) foot bankhead and revetment.

(c) It is understood that the contractor has personally visited the location of the work and has familiarized himself with the difficulties to be encountered in the execution of the contract, including depth of water, lengths of piles required, availability of material and uncertainties of weather and other contingencies.

##### 3. Drawings.—

4. **Mattress.**—(a) The mattress shall be fabricated from live, bar growth willow brush cut not more than two weeks prior to use, having a butt diameter between one (1) and two and one-half ( $2\frac{1}{2}$ ) inches, and the length exceeding ten (10) feet. The limb growth shall be stripped from the lower half of the stem. The use of a small percentage of young cottonwood mixed with the willows is permissible.

(b) Temporary anchor piles, to be removed after they have served their purpose, shall be driven near the edge of the mattress so spaced as to hold it safely in position during construction and to guide it to position on the bottom of the river when being ballasted.

(c) In starting the mattress a header shall be formed across the head of the mattress with a brush bundle fifteen (15) inches in diameter, wrapped with four wraps of No. 12 galvanized wire at intervals of three (3) feet. Butts of willows for weaving shall be thrust diagonally through the header roll, and securely fastened with No. 9 galvanized wire. The willows shall be plaited over and under in basket fashion to

produce a tightly woven brush surface free from open interstices, *the willow tops lying underneath*. Before weaving the mattress, snags, logs or other obstructions, which might prevent it from lying evenly in contact with the river bed, shall be removed.

(d) At the head of the dike the bank is to be sloped three (3) horizontal to one (1) vertical. The mattress is to be a continuation of the mattress extending from the bank-head and carried downstream on line with the dike. It shall be woven around the piles extending fifty (50) feet outside the outside or stream row of piling, through the dike proper, and twenty (20) feet inside the inside or land row of piling, making ninety (90) feet in width from edge to edge of mattress. When the dike is complete the mattress shall extend fifty (50) feet below the last pile bent at the downstream end.

(e) The mattress shall be woven to a full twelve (12) inch thickness, of close weave and tight stitch, and shall have a selvage border which shall be formed by plaiting the willow tops into the weave at the edge of the mattress so there will be no loose ends. The mattress shall be of continuous weave throughout, unless conditions require that it be woven in sections, in which case each section must lap at least thirty (30) feet over the preceding section. Construction in sections shall not be allowed without the approval and sanction of the Engineer. No additional payment will be allowed for overlapping.

(f) The mattress shall be reinforced with continuous lines of three-eighths ( $\frac{3}{8}$ ) inch strand cable, composed of seven (7) No. 11 wires, laid in pairs on top and underneath, and spaced sixteen (16) feet apart longitudinally and transversely. At each intersection the four cables shall be tightly drawn through the mattress with a toggle hook made for that purpose and fastened with a four part "U" clip. Free ends of strands shall be clipped together in pairs at the selvage with "U" clips.

(g) If the Engineer so directs, a line of poles shall be lashed across the extreme downstream end of the mattress, and a parallel row 16 feet back from this end with longitudinal poles 16 feet centers reaching between them forming cribs 16 feet square. This is to keep the stone from slipping off the end of the mattress if it would be likely to take a steep slope owing to under-scouring at the end. The poles across the end shall be two (2) high, but the others one (1) high. The poles shall be straight and of good timber, not less than six (6) inches in diameter at the butt and three (3) inches in diameter at the top. The poles shall lap at end two (2) feet or more and be fastened securely to the mattress with three-eighths ( $\frac{3}{8}$ ) inch galvanized strand.

(h) Stone shall be evenly distributed upon the mattress for sinking in such manner as to cause it to establish contact with the river bed throughout, in the quantity of not less than one (1) ton per square (100 square feet) of mattress.

(i) If the mattress be injured by floods, driftwood, or otherwise during construction or sinking, the contractor shall repair or replace the damaged or destroyed portions without charge as directed by the Engineer.

5. **Stone for Ballast.**—All stone for ballasting the mattress shall be hard, sound, clean material that will withstand the action of the elements, and the weight of any stone shall not be less than twenty-five (25) lb. nor more than one hundred twenty-five (125) lb.

6. **Dike Piling.**—All piling must be of untreated cypress cut above the ground swell from sound live timber not more than six months before delivery. They shall be sawed square across the butt, bark peeled and the limb growth shall be cut close and smooth. They shall have a butt diameter between twelve (12) and fifteen (15) inches, a tip diameter not less than seven (7) inches and shall taper uniformly between butt and tip. They must be free from rot, loose or decayed knots, wind-shakes or other defects which would render them unsuitable for the use intended. They must be straight, in no case curving more than one fourth ( $\frac{1}{4}$ ) inch per foot of length with maximum deflection near the mid-length. Curvature in more than one direction or short bends will be sufficient cause for rejection. Each pile driven shall be sharpened to a point three (3) inches in diameter (or square) and the length of scarf shall be about one and one-half ( $1\frac{1}{2}$ ) times the diameter of the pile before pointing.

7. **Dike Construction.**—(a) The piles shall be driven to a least penetration of twenty (20) feet, and shall be forty (40) to sixty (60) feet in length. The tops of the piles, when driven, shall be at same elevation, as the top of the bank, which has an average elevation of about (...) feet above zero of the gage, unless the Engineer shall deem it necessary or expedient to vary the height to suit conditions; but no change in the specified height of the dike shall be made without the written consent of the Engineer. Piles shall be driven, as nearly plumb as it is possible to drive them from a river driver

in deep water, in bents of three piles to the bent, ten (10) feet apart, and the spacing of the bents shall average not more than ten feet, center to center, for the length of the dike. If necessary to secure adequate penetration of the piles without injury to the pile heads, a water jet shall be used in conjunction with the hammer. All piles shall be cut off square at the elevation of the determined height of the dike and the top row of bracing shall be placed so that the top edge of the braces are not more than two (2) inches below the top of the piles.

(b) After driving, the piles shall be braced transversely and longitudinally as shown on the plans. The transverse bracing shall consist of a double line of four (4) by eight (8) inch timbers twenty-two (22) feet long near the top of the pile, a similar set of bracing as nearly twelve feet below the top bracing as stage of river will permit and two diagonal braces four (4) by eight (8) inch by twenty-six (26) feet long, extending from the lower side of the top bracing to the upper side of the bottom bracing on opposite sides of the piles. The ends of the horizontal transverse bracing shall be placed and the corners of the diagonal transverse bracing shall be sawed off flush with the outer face of the stream row of piling.

(c) The longitudinal bracing shall consist of a double line of bracing near the top of the piles, and a double line of bracing below the top on the two outside rows of piling and a single line of bracing near the top of the piles and a single line of bracing below the top on the middle line of piles. The spacing between the top and bottom lines of bracing will be governed by the spacing of the transverse bracing, but it is desired that the average spacing between top and bottom bracing shall be as near twelve (12) feet as stage of water will permit. All longitudinal brace timbers shall be four (4) by eight (8) inch, all twenty-two (22) feet long. The lap of the brace timbers at the top of the piles in each row shall alternate with the lap of the timbers below. All brace timbers shall be long leaf pine, square edged and sound and of dimensions as specified.

(d) The brace timbers shall be through bolted and tightly drawn with three-quarter ( $\frac{3}{4}$ ) inch bolts, having washers on each end of the bolt. The single line of bracing on the middle row of piles shall be placed alternately on opposite sides of the piles in each double panel so that one bolt will hold at the lap.

(e) The bracing at the tops of the piles, both transversely and longitudinally, shall be done before weaving of the mattress is begun and if stage of river is such that the lower bracing will not materially interfere with weaving of the mattress, the lower bracing shall also be placed. If the lower bracing cannot be placed without interfering with weaving of the mattress, there shall be temporary bracing applied if needed in addition to the top bracing to hold piling in proper position and the permanent bracing applied after the mattress is sunk.

8. **Screens.**—(a) A continuous row of poles is to be laid on the mattress after it is woven and securely fastened to it with No. 9 galvanized wire in contact with the inside of the bank row of piling. The dike shall then be screened with willow or cottonwood poles, spaced about one-foot centers along the bank side of the dike for its entire length. The butt ends of the poles shall be sharpened and driven through the mattress in contact with the longitudinal row of poles and securely nailed to the same. After the mattress has been sunk and thoroughly settled on the bed of the stream, the poles shall be spaced and nailed to the top and bottom lines of longitudinal bracing and sawed off even with the top of the dike. They shall be of such lengths that when the mattress has been thoroughly settled, the diameter of the pole, where nailed to the top bracing, shall not be less than two (2) inches.

(b) After the dike has been finished the stream row of piling shall be sheathed on the outside and between the top and bottom lines of bracing with four (4) by eight (8) inch timbers twenty-two (22) feet long.

9. **Header.**—As soon as the dike has been started and the first bents have been braced, a header shall be built close up against the first bents. A trench about thirty (30) feet square shall be excavated between the pile bents and the top of the slope, to the level of extreme low water in the stream, into which the edge of the dike mattress shall be sunk. The hole shall then be refilled with alternate layers of brush and stone, each three-foot layer of brush to be covered with a closely packed layer of one-man stones, to the height of two feet above the top of the dike in order to allow for settlement. The cost of the header shall be included in the price bid per linear foot of dike.

10. **Bankhead and Revetment.**—Above the upstream end of the dike, a bankhead and revetment, as hereinafter described, shall be built and form an integral part of the dike. The cost to the Railway Company for same shall be a lump sum price as bid by the Contractor for said bankhead and revetment.

Above the dike mattress and immediately adjacent to same the river bank shall be sloped to a slope not to exceed three horizontal to one vertical for distance of about seventy (70) feet from upstream end of dike mattress. The high point of surface of said slope to be at least 36 inches below extreme low water of river; thence a hole in river bank not less than thirty (30) feet wide parallel with bank of river and extending streamward sufficient distance to extend into extreme low water shall be excavated. The bottom of same to be as low as extreme low water on river bank and river side to be at least 48 inches below extreme low water in river. The entire area of bottom of hole shall be paved with good heavy-one-man stone. Then from upstream side of bankhead a standard mattress shall be laid, the shore edge of same overlapping on stone paving in bottom of hole a distance necessary to prevent any chance of scouring, said mattress shall be of such length that the distance measured along the slope and bottom of hole from the upstream side of bankhead to junction with upstream end of dike mattress shall not be less than one hundred (100) feet. The hole shall then be filled with alternate layers of brush and stone, each layer of brush being not more than three (3) feet thick and covered with closely packed layer of one-man stone. The stream or river side of brush and stone filling of bankhead is to extend over and rest upon shore edge of mattress a sufficient distance to provide a good substantial bond between bankhead and mattress.

The pavement shall consist of stone, rectangular in shape, laid on edge parallel to the bank of the stream and shall be not less than one-foot thick measured normal to the slope. It shall be a continuation of the final layer of stone in bankhead and shall extend not less than eighteen (18) inches riverward from the inshore edge of the mattress. Beyond this a strip of mattress twelve (12) feet wide shall be covered with a compact layer of stone one-foot thick by casting into the water. Previous to paving, the inshore edge of the mattress shall be filled with spalls or quarry chips flush with the top of the mattress and running out to zero thickness six feet up the slope. After the pavement is laid, spalls and quarry chips shall be spread over the surface to fill all interstices. The mattress shall be the standard mattress hereinbefore described, and shall be well weighted with stone. The paving and mattress shall flare upstream from a line normal to the bank and the downstream edge shall be connected to the dike mattress in such manner that it will be a continuation of the dike mattress.

11. **Measurement.**—The length of the diversion dike shall be measured on a straight line of one elevation along its center from the center of the first bent upstream to the center of the last bent downstream, and payment will be made at the price bid per linear foot for the total length to the nearest foot as thus measured.

12. **Final Examination and Acceptance.**—As soon as possible after the completion of the entire work it will be thoroughly inspected by the Engineer, and if found to be constructed in accordance with the plans and specifications, and is otherwise satisfactory, will be finally accepted. All work not fully in accordance with the specifications, shall be repaired to the satisfaction of the Engineer, at the Contractor's own expense, and final payment will be retained until the work has been satisfactorily completed.

13. **Conduct of the Work.**—(a) The contractor will use due diligence and despatch in the execution of the work to the end that the work will be completed in a first class and workmanlike manner. He may be required to suspend work at any time when, for any reason, the stage of the river, its velocity, or the presence of drift, appear to be detrimental to the best results.

(b) It is mutually understood that time is the essence of the contract, and that the work shall be completed in the quickest time possible; and the Contractor will be required to maintain a force sufficient to complete the work in the shortest time possible.

(c) The Contractor shall familiarize himself with the regulations of the Department of War of the United States as affecting the control of inland waterways and shall not do, or permit to be done, anything or operation that shall be in conflict with said regulations. During the progress of the work, he shall not cause to be dumped, thrown overboard, sunk or misplaced any material, plant, machinery or appliances, that may cause a dangerous obstruction in channel of the river, and he shall promptly remove any such article upon request of the Engineer.

(d) Should it become necessary to occupy private property in the execution of the proposed work, the Contractor shall obtain the written consent of the owners before entering upon said property, and shall relieve the Railway Company from liability for the use or misuse of said property.

(e) The Contractor shall provide, as becomes necessary, proper lights each night, between the hours of sunset and sunrise, on all floating plant connected with the work, and shall be responsible for all damages resulting from any neglect or failure in this

respect. If work at night is permitted by the Engineer, the Contractor shall maintain, from sunset to sunrise, such lights on or about his plant which may be deemed necessary for the proper observation of the construction operations.

14. **Minor Modifications.**—It is the object and intent of the plans and specifications to produce a diversion dike complete in every respect. Should any minor changes in the execution of the work be deemed necessary or expedient to carry out the intent of the contract, the Company reserves the right to order such changes, provided the unit cost of the Contractor for doing the work shall not be increased thereby. No change, which will materially affect the cost of doing the work, shall be made, and no greater or lesser unit price paid, except upon formal written agreement between the parties to the contract.

15. **Inspection.**—The work will be conducted under the general direction of the Engineer, whose Inspector, appointed by him, shall enforce a strict compliance with the terms of the contract, but the presence of the Inspector shall not relieve the Contractor of any responsibility for the proper execution of the work. He shall furnish all facilities such as the use of boats, boatmen, laborers and materials, forming a part of the ordinary and usual equipment, as may be reasonably necessary, in inspecting and supervising the work, and it shall be understood that the cost of meeting all these requirements must be included in the price bid.

#### Appendix D

##### (5) TYPES OF BULKHEADS, JETTIES AND SEAWALLS, GIVING CROSS-SECTION OF EACH AND STATING THE PURPOSE WHICH THEY SERVE, INCLUDING COMPARISONS OF FIRST COST, SERVICE LIFE AND MAINTENANCE COST OF THE VARIOUS TYPES

W. G. Brown, Chairman, Sub-Committee; R. E. Fristoe, H. F. Sharpley.

Your Committee has collected quite a mass of data from which a full report will be made next year.

Having this in mind, your Committee has devoted its efforts to collection of data for study and assimilation into a comprehensive report, and can now only report progress, with the request that the subject be continued.

#### Appendix E

##### (6) TYPES OF FENDER SYSTEMS FOR PROTECTING WHARVES AND RECOMMEND SUITABLE USES FOR EACH, INCLUDING COMPARISONS OF FIRST COST, SERVICE LIFE AND MAINTENANCE COST OF THE VARIOUS TYPES

Benjamin Elkind, Chairman, Sub-Committee; W. G. Brown, R. E. Fristoe, E. H. Roth, C. U. Smith.

Fenders prevent injury by abrasion, avoid damage caused by chafing of vessels against wharves, absorb the energy of impact of vessels coming in contact with wharves and protect the structures from violent sea action in exposed locations. Fenders are fitted so that they can readily be removed for repair and replacement.

The design of fenders is partly of a local nature and there is much scope for the exercise of individual judgment. Dangerous shore eddies, range and duration of tide, absence or presence of waves, swells, currents and ice, existence of worms and insects which attack timber, etc., are purely local. The design of fenders depends on the types of the wharf to be protected, the manner of berthing, the operation of loading and discharging cargo, and the size of the vessel.

A vessel weighing 5,000 tons and moving at a rate of one-half ( $\frac{1}{2}$ ) mile an hour has a kinetic energy of about 45-foot-tons. With double the weight and velocity, the energy is almost 340 foot tons. The fenders must expend this amount of work without injury to either the ship or the wharf. Wooden pile structures because of their elasticity are generally protected by fenders against abrasion. Steel, masonry and concrete wharves are usually provided with fenders with sufficient give to save the main structure from shock of vessels coming alongside. There are many examples, however, of rigid wharves on which the fenders are compressible only to the extent furnished by timber fixed or suspended from the face of the structure.

Fenders are grouped into three (3) general types—fixed, spring, and floating.

### Fixed Fenders

Fixed fenders may be constructed of piles, vertical or horizontal strips or sheathing or a combination of all or any of the foregoing. Long horizontal strips of heavy timber are not desirable. Vertical chocks should be fitted in at frequent intervals to prevent tugs or similar vessels having considerable sheer from catching under the horizontal strips and thus ripping them off. The outer corners of piers are usually protected by heavy clusters of fender piles or by separate pile clusters and are kept in place by chains or wrapped with wire cable, rather than bolts, to facilitate replacement. White oak piles where obtainable, are generally used in fenders as they better resist abrasion.

Timber is subject to dry and wet rot and to the depredations of worms and insects. Dry rot is a disintegration of the fibres accompanied by the growth of a fungus. It is due to, and accelerated by, inadequate ventilation, and the only efficient preventative is thorough ventilation. Wet rot is a decomposition of the fibres under moisture, and to prevent this it is essential to avoid water pockets and to have a rapid runoff. Destructive marine life of one form or another thrive in nearly all salt and brackish water harbors in this country. The usual practice is to impregnate the timber to a sufficient depth with a preservative to resist the action of these influences.

On the Great Lakes where tides and currents do not enter into navigation problems to a great extent, the practice has been to use very simple fender systems, even going so far at times as to construct a concrete docking face with a steel rail imbedded in the face as a guard. Some docks have one or two courses of oak fenders set into the face of the concrete and the theory appears to be that the boat crews must handle their vessel at such speeds as to protect themselves in berthing.

During the past ten years the Lake Carriers Association have been recommending that a wood fender be secured to or set into the concrete fender to afford a buffer for the vessels. Some of the newer docks are being built with an oak timber varying from 16 in. to 24 in. in width set into the concrete fender to protect the vessel sides. These oak pieces are held in place by bolts set in the concrete, the nuts being countersunk in a recess to protect them from damage by vessels. This permits the replacement of the timbers when worn out. On some of the older docks as well as the lock walls of the canal at Sault Ste. Marie, Mich., oak fender wales are being applied, the most acceptable method being the drilling of the face of the fender wall and anchoring with expansion bolts, two 4-in.  $\times$  4-in. steel angles 12 in. apart. A 12-in.  $\times$  12-in. oak timber is placed between these angles and secured by bolting the timber through the two angles. Two lines of these timbers are placed 12 in. apart and a third timber secured between the first two by vertical bolts. This gives a 3-ft. wide wood fender to protect the vessel.

In some instances on the Great Lakes, wood fenders have been applied to old structures by fastening them with expansion bolts drilled into the concrete, countersinking the nut into the timber as outlined above. These wood fenders have a life of approximately

10 years, depending upon the density of the traffic. In addition to the above, pile clusters have been driven at the outer corners of docks to prevent the vessels from striking the dock and to be used by vessels to lie against in turning at the end of the dock. These pile clusters are wrapped with old wire cable. The piles should be treated above the water line. These pile clusters fail by breaking off at the ground line and are hard to replace because the stubbs cannot be jetted out without danger of undermining the foundation of the dock. By treating the piles in this manner it is to be expected that they will break off in the treated area.

Fig. 1 and 2 illustrate the latest fender construction of steamship wharves in New York Harbor. This type was used in a recently completed Erie Railroad structure in Jersey City known as Pier No. 8. The wharf is 1,000 feet long and 70 feet wide and is

enclosed with a concrete wall, retaining a cinder fill on timber decking, supported on untreated timber piles. The superstructure consists of a three-story steel frame shed and two (2) service tracks extending the full length. The depth is maintained to 33 feet below mean low water level. Scows, tugs and ocean freighters are handled at this pier. All the timber, except the backlogs, in the fenders are white oak. The timber is untreated except for the pile tops which are protected with white lead and oil paint. This

Fig. 3

Fig. 4

Fig. 5

Fig. 6

Fig. 7

harbor, on account of the sewage, is not infested with marine borers. The portion of the piles above low water is the only part which decays but was not impregnated on account of the fire risk. It will be noted that the river end has vertical oak strips to resist shearing from tugs, scows and square cornered vessels. This is not necessary along the sides of wharves on account of the narrow slip. The fender system is fastened to the concrete wall of the structure with screw anchors which permit ready replacement. The oak fender strip is securely fastened by spikes to the backlogs.

Fig. 3 illustrates a removable fender for the concrete Bird Island Pier at Buffalo, N. Y. On account of the severe ice conditions and the shutdown of navigation in winter, it is desirable that the timber fenders be readily removable. The lower part of the wall proper is of precast concrete blocks and the upper of concrete poured in place. The fender system consists of vertical 8 in.  $\times$  10 in. timbers, with an upper 6 in.  $\times$  10 in. continuous wale and a rubbing face of 4 in.  $\times$  12 in. boards. Recesses are cast in the blocks and left in the upper section of the wall at every fender, and at these recesses an iron hook is embedded protruding up into the opening. Every fender has two looped bolts passing through it which hook over the embedded iron, the fender being cushioned from the concrete face by the interposed horizontal wale. Alongside of each fender are fastened structural angles, forming grooves which act as guides for the rubbing timbers. The fender can be taken down by being lifted in sections from the hooks and similarly returned when its protection is again required. Rubbing boards can be replaced by slipping the damaged unit out of the guides and dropping a new one in, without any carpenter work or repair on any other part of the structure. (For additional information see *Engineering News-Record*, August 12, 1920).

Fig. 4 illustrates fender construction as more commonly used. It shows the framing, fender pile and belay pile as generally used for tying up boats in 30 to 40 feet of water where tides and currents are not usually severe.

Fig. 5 illustrates the use of short or stub fenders by the Oakland Port Commission, Oakland, Cal., where the water is sufficiently deep to justify hanging the fenders from the wharf. The dummy piles reach below low water and have the bottom end beveled to prevent possible uplift from floating timber or a boat guard rail. Sometimes, to take the wear from the rubbing of the guard rails of the boats, untreated sheathing 6 in.  $\times$  8 in.  $\times$  20 ft. is spiked at 45 degrees with the horizontal to the dummy piles which hang from the ribbing and alternate with the treated piles on the inside face of the slip.

### Spring Fenders

Spring fenders employ the use of coil springs or groups of heavy springs, where rough water or strong current is prevalent; this type permits vessels coming along side without damaging the structure.

Fig. 6 illustrates an example used at Los Angeles Harbor, Cal. The fender piles are supported from the cap timbers by coil springs, the piles being driven 8 ft. apart along the jetty, the pile heads bearing against a waling composed of three timbers bolted together. Between this waling and the capping of the jetty, three coil buffer springs were placed. The springs were fitted with a  $\frac{1}{2}$ -in. thick mild steel bearing back and front, the plates being 8 in.  $\times$  12 in. The diameters of the coils are  $\frac{5}{8}$ -in.,  $\frac{3}{4}$ -in. and 1-in. respectively. Though the springs appear somewhat light, the arrangement has proven satisfactory at this location.

Fig. 7 is an example of an alternative arrangement in which leaf springs are used in groups of four. The load sustained by each spring being four tons, the total resistance available ultimately to bring the vessel gently to rest is 16 tons at each bay of 10 feet.

### Floating Fenders

A floating fender often consists of rolling logs or of single or made-up timbers fastened at the ends with lines or chains fixed to the side of the wharves. Floating fenders consisting of round logs or rafts built up of timber are more suitable for masonry walls than for pile structures, as they cause rapid wear of the piles. This is particularly un-

desirable where the piles are treated, as the marine borers attack them as soon as the treated exterior portion is worn through. Compressible fenders made of bundles of saplings bound with wire are used on the large concrete pile pier at Halifax.

## Appendix F

### (7) WAREHOUSE PIERS, COAL AND ORE PIERS, CAR FLOAT PIERS AND OTHERS, WITH RECOMMENDATIONS AS TO THE TYPE SUITABLE FOR USE UNDER VARYING CONDITIONS, INCLUDING COMPARISONS OF FIRST COST, SERVICE LIFE AND MAINTENANCE COST OF THE VARIOUS TYPES

R. C. Young, Chairman, Sub-Committee; W. G. Brown, E. H. Roth, H. F. Sharpley.

#### Coal and Ore Piers

From the beginning coal and ore wharves or piers on the Great Lakes have been commonly called docks.

The first dock designed for the shipment of iron ore was built at Marquette Harbor in 1855. It was built about  $4\frac{1}{2}$  ft. above the water in the form of a wharf. The ore was wheeled aboard the vessels with wheel barrows 30 men loading a 300-ton vessel in from three to six days. The ore was transported to the dock in 4-wheeled flat bottomed cars carrying about three tons each and drawn by mules. The ore was shoveled from the cars from a trestle about 8 ft. above the deck of the dock.

There are two general classes of coal and ore docks (or piers), viz.: Docks designed to load ore or coal into vessels and those designed to receive the same commodities at the delivery port.

#### Ore Loading Docks on the Great Lakes

These docks are so constructed that the hopper bottom cars into which the ore is loaded at the mines are pushed to the top of the dock over an inclined approach, dumped into pockets and from there through chutes into the vessel.

The first ore dock of this nature was built of timber in Marquette, Mich., in 1857 and the deck was 25 ft. above the water. As the small sailing vessels were replaced by larger sailing vessels and steamers the size of the timber docks was increased to a height of 73 ft. above the water. About 1911 the D.M.&N. Ry. at Duluth, Minn. and the D.&I.R. Ry. at Two Harbors, Minn. began to replace their timber docks with steel structures placed on concrete foundations. The same year the Great Northern Railway built a similar steel ore dock at Allouez Bay, Wisconsin. In 1912 the Lake Superior and Ishpeming Railway built the first reinforced concrete dock to replace their timber structure. Since 1912 the ore dock construction on the Great Lakes has been largely of a permanent nature. The Northern Pacific, the Soo Line and D.S.S.&A. Ry. have all built reinforced concrete docks. These are of a different design, however, than the one built by the L.S.&I. Ry. and now most of the ore shipping docks on the Great Lakes are either of steel with concrete foundations or all of reinforced concrete. Other railroad companies, however, are still building modern, electrically operated docks of timber which are quite efficient and economical.

These docks are composed of two rows of pockets or bins sloping from the center toward the outside; the slope of the pocket bottom varies from 45 degrees to 48 degrees.

These pockets are spaced 12 ft. center to center longitudinally and usually have two railroad tracks over each pocket or four tracks in all. The pockets hold from 250 to 400 gross tons of iron ore each. Each pocket is equipped with a steel chute about 32 ft. long and about 7 ft. wide at dock end and 5 ft. wide at delivery end. The flow of ore is controlled by gates or doors, both the chute and pocket door are operated by an electric motor, each motor is arranged to operate from 6 to 10 chutes and pocket doors. These docks are well lighted by electricity so that loading can be carried on during the entire 24 hours.

The general dimensions of the permanent ore docks are—

|                                  |                   |
|----------------------------------|-------------------|
| Height from deck to water .....  | 75 ft. to 85 ft.  |
| Width out to out at deck .....   | 54 ft. to 62½ ft. |
| Width out to out at fender ..... | 60 ft. to 68 ft.  |

The number of pockets vary from 150 to 384.

## Foundations

The foundations of the permanent docks are of three general types, viz.:

**CRIBS.**—Where the material in the harbor is clay, the site is dredged to a safe point below any possible expected harbor depth and two lines of timber cribs built to the height of low water datum, one on each side of the dock. These cribs are filled with rock which is covered with canvas and concrete slab foundation placed on each side and tied together frequently with concrete beams. The vessel fenders are built on each side as a part of the concrete slabs and the piers supporting the dock columns are placed thereon.

**OPEN PILE FOUNDATION.**—The piles in this foundation are driven in bents about 4 ft. apart; at every alternate bent batter piles are driven to take care of the sway. About every 120 ft. rectangular cribs are formed by driving sheet piling the width of the dock and about 24 ft. lengthwise of the dock. These cribs are tied together with rods and filled with sand or rock. The piling and sheet piling is cut off to low water datum and a reinforced concrete slab placed on each side and tied together frequently with reinforced concrete beams. The vessel fender is built into this slab as are the piers carrying the columns supporting the superstructure.

**CLOSED TYPE PILE FOUNDATIONS.**—In this type the piles are driven the same as in the open type, wale timbers are placed around the entire foundation and it is enclosed with sheet piling, either wood or steel. The foundation is tied together with 1½ in. steel turnbuckle rods; the piling and sheet piling cut off at low water datum and the whole foundation filled with sand dredged from the harbor.

In the case of the L.S.&I. dock, the entire pile foundation is covered by a combined slab and fender while some of the other docks have a slab the same as described in the open pile foundation and crib foundations.

All piling and timber is untreated and is safe from decay indefinitely below a point 15 in. above mean water level datum.

At Norfolk, Va., the Norfolk and Western Railway have built similar piers for loading coal into vessels, as follows:

### LAMBERT'S POINT, VIRGINIA—FACILITIES—

#### Coal Pier No. 4

Length—1200 ft.

Width—68 ft.

Height above mean low tide—91.5 ft.

No. of chutes on each side—31

Length of adjustable chutes—33 ft.

Spacing center to center of pockets—30 ft.

Capacity of pockets in tons—144 each.

Height of bottom of pockets above mean low tide—68 ft.

## LIST OF ORE LOADING DOCKS ON THE GREAT LAKES

| RAILWAY                            | LOCATION           | Dock No. | Number of pockets | Capacity per car | Gross capacity in tons | Clearance from bottom of pocket to center of mill-rail | Height of water to dock | Width of dock | Length of dock | Length of apron | Length of Dock | Angle of Pocket          | Date of construction |
|------------------------------------|--------------------|----------|-------------------|------------------|------------------------|--------------------------------------------------------|-------------------------|---------------|----------------|-----------------|----------------|--------------------------|----------------------|
| Chicago & Northwestern Ry.         | Escanaba, Mich.    | 5        | 370               | 5 at 50 tons     | 92500                  | 4142                                                   | 37'-9 5/8"              | 70' 9"        | 51' 6"         | 32' 1 1/2"      | 2220'          | 45°-0'                   | 1910                 |
| "                                  | "                  | 6        | 320               | 5 "              | 80000                  | 4260                                                   | 40' 0"                  | 73' 1 1/2"    | 51' 6"         | 35' 4"          | 1920'          | 45°-0'                   | 1925                 |

The variation of the tide and the listing of the vessels is taken care of by the adjustable chutes. These chutes are raised and lowered as the occasion demands by manually operated windlass.

The road cars are pulled upon what is known as an electrically operated dumper by Barney cars, thence the road cars are dumped into pier cars, each holding 100 tons. These pier cars are electrically operated and are moved forward under their own power to an electric elevator where they are elevated on top of the pier at an elevation of 91.5 ft. above mean low tide. Pier cars are thence moved forward to the various pockets and are dumped automatically by an air operated tripping device. There are two dumpers located on the land end of this pier which have a capacity of dumping one road car about every  $1\frac{1}{4}$  minutes.

#### COAL PIER No. 3

Length—860 ft.

Width—58.5 ft.

Height above mean low tide—77 ft.

No. of chutes on each side—30 ft.

Length of telescopic chutes—33 ft.

Spacing center to center of pockets—25 ft.

Capacity of pockets in tons on each side—10 tons.

Height of bottom of pockets above mean low tide—44 ft.

This coal pier has one electrically operated dumper on the land end and can be operated similar to the above mentioned coal pier No. 4. However, in recent years the Company has arranged to operate road cars directly upon this pier from where the road cars are dumped directly into the pockets, from which pockets the coal is transferred to the vessels by telescopic chutes.

Coal Pier No. 3 has a vessel docking capacity of 4 of the smaller type or 2 larger and 2 smaller ocean vessels, while Coal Pier No. 4 has a vessel docking capacity of 4 of the larger oceangoing vessels.

The railway company has 3 at Lambert's Point, Pier S being described below.

Length—1200 ft.

Width—222 ft., including two 7 ft. apron platforms on each side.

Housed width—208 ft.

On the center of this house are 4 depressed tracks, capacity 100 cars.

On each side of the house are adjustable ramps which can be raised or lowered according to the listing of the vessels. These ramps are equipped with escalators.

Docking capacity on each side is two vessels and if necessary one on the outer end.

At Sewell's Point, Virginia, the railroad also owns and operates two warehouses and one grain elevator.

Grain elevator storage capacity in bushels is 750,000.

Length of docking space—1400 ft.

Maximum capacity of grain handling per hour—50,000 bushels.

Height of grain galleries above mean sea level datum—71 ft.

No. of chutes for loading vessels—3.

Warehouse pier at Sewell's Point docking space—2400 ft.

Width of houses—99 ft.

Car capacity of tracks in rear of the two houses—120.

Car capacity of tracks on apron platform—224.

The warehouses at Sewell's Point are reinforced concrete type construction supported by concrete piles, while the warehouses at Lambert's Point are supported on steel cylinders filled with concrete. These steel cylinders support the main columns of the structure proper. The floor system of the entire warehouse is supported on creosoted wooden piles varying in length from 75 ft. to 110 ft.

The coal piers are supported by steel cylinders filled with concrete and the main floor system is supported on creosoted wooden piling throughout.

For the oceangoing vessels the Railway Company maintains the slips to a depth of 35-ft. below mean low tide, and for coastwise vessels a depth of 25-ft.

## Ore Unloading Docks and Coal Unloading Docks

These docks are of the same general type and can be described very briefly. They are usually designed to carry an unloading crane. They can be built either parallel to shore in the form of a wharf or at right angles to shore in the form of a pier. If in the form of a pier, the general method of construction is to drive a row of piling about 4 ft. centers enclosing the proposed structure, a row of Wakefield or other approved sheet piling is then driven enclosing the whole area. The foundation is then tied together with 1½ inch turnbuckle rods below the water line. If it is to be a wood structure the piles and sheet piles can be cut off about 7 ft. above the water level and suitable wale strips be applied for vessel fenders; the whole structure is then filled with sand by use of a dredge.

The area is decked or not, depending upon the use to be made of it.

The foundations for crane rails can be made by driving piles for supports to the crane rail timbers.

A dock can be constructed in this manner and used successfully until the timber and piling above water is decayed. It can then be cut off at water line, a few piles driven to support the back of the concrete wall and a concrete fender wall can be built from water line to top of dock which makes a permanent structure, or if a permanent structure is contemplated in the first place, the piling can be cut off at the water level and the concrete fender built in the first instance.

If the dock is to be built parallel to the shore, the construction will be the same as above except that anchor piling should be driven about 30 ft. back of the face of the dock and the anchor rods installed there to hold the face of the dock from bulging.

In rivers or harbors where the waterway cannot be restricted docks are sometimes built with a reinforced concrete floor resting on piles so as to allow the water to pass under it. The fender or vessel wale is so designed that the strain or shock is carried through the fender and floor to the shore. The floor is filled with suitable material to the top of the fender. Various kinds of unloading cranes or bridges are used to remove ore or coal from the hold of the vessel, clam shell buckets from 3 to 15 tons capacity are used. At Alpena a limestone dock or pier, similar to the iron ore docks is used to load limestone into vessels. At Inland Harbor, Michigan, the Inland Steel Company has a dock or pier for loading crushed stone into vessels. This structure is similar in construction to the piers built for unloading of iron ore and coal, except that it is somewhat higher and has trap doors in the deck which allows the different grades of crushed stone to drop through onto a belt conveyor running lengthwise with the pier. This conveyor deposits the stone on to lateral conveyors which carry the stone into the vessel.

At many of the lower lake ports docks for loading coal into vessels are built similar to the coal and ore unloading docks, except they are equipped with mechanism for lifting up the gondola cars of coal, turning them bottom up and dumping them into a container which is then lowered into the vessel hold and dumped.

## Comparative Costs

In 1911, a study was made of construction and maintenance costs of three types of iron ore loading docks on the Great Lakes, not including the approach structure, with the following results:

|             |              |
|-------------|--------------|
| Cost—Timber | 100 per cent |
| Concrete    | 167 per cent |
| Steel       | 187 per cent |

Maintenance over a 30 year period, which contemplates a life of from 15 years to 20 years for a timber dock and writing off the entire investment in 30 years is as follows:

|                    |              |
|--------------------|--------------|
| Maintenance—Timber | 100 per cent |
| Concrete           | 70 per cent  |
| Steel              | 76 per cent  |

### Coal and Ore Piers on the Pacific Coast

The superstructure of coal and ore piers is not here discussed as the design is more or less individual as determined by the requirements of each location. The foundation must be planned for heavier loads than is the general practice in wharf design, and this added foundation strength is often secured by placing timber cribs filled with rock.

Another type of foundation used for ore docks is thickly driven piling. A concrete bulkhead may be constructed on the channel side and strengthened with tie rods carried across to piling on the opposite side of the pier. The pier may be built on piles driven so close together as to form suitable foundation for a reinforced concrete mat or blanket over the entire foundation area. If the piles are driven in water, sand may be filled in to low water or to the height at which the piling can be conveniently cut off for the placing of a reinforced concrete blanket.

### Appendix G

#### (10) ECONOMIC PRINCIPLES INVOLVED IN CLEARANCES OVER NAVIGABLE WATERWAYS

Robert H. Ford, Chairman, Sub-Committee; D. J. Brumley, G. S. Fanning, W. D. Faucette, R. A. Feldes, F. G. Jonah, C. S. Kirkpatrick, G. J. Ray, J. E. Willoughby.

The actual and proposed development of inland waterways in the United States has the effect of placing an increased burden upon the operations of land transportation and facilities. This can usually be traced to excessive clearance requirements for bridges spanning inland streams which are considered as navigable.

A study of typical cases has been made and in practically every instance it has been found that the clearances required and demanded are unduly excessive and unnecessary in the light of modern tendencies in watercraft design, construction and operation.

It has also been found that the requirements for these unnecessary clearances largely result either from a lack of proper data or from a failure to appreciate the various factors which must be considered before proper clearances can be determined in the interest of both land and water transportation.

Proper clearances for naturally navigable streams are those which will not unduly interfere with the operation of either land or water transportation, cause unwise expenditures to be made for physical readjustments, or place burdensome restrictions on their future expansion. There must be an economic balance in the interest of both forms of transportation.

While adequate information is not yet available to enable a forecast to be made as to the result of these burdensome restrictions on rail transportation, from certain data which has been made available to us we conclude that the excess annual cost to the railroads of the United States represents a sum, which when capitalized at 5 per cent, amounts to at least Two Hundred Million Dollars.

We are collecting information on these and similar questions and expect to report a formula which can be used as a guide to a proper approach to problems of this character and thus permit a better understanding of the subject than appears generally to exist at present. We are also contacting with various other scientific organizations which are working on various aspects of this problem.

### Appendix H

#### (11) COST TO RAILWAYS FOR CONSTRUCTION, MAINTENANCE AND OPERATION OF BRIDGES OVER NAVIGABLE WATERWAYS

- (a) in the natural condition of stream.
- (b) additional costs brought about by the enlargement of the capacity of the streams over and above their natural conditions.

F. E. Morrow, Chairman, Sub-Committee; W. H. Courtenay, L. G. Curtis, I. W. Geer, G. F. Hand, J. R. Hickox, C. F. Loweth, G. R. Westcott.

Your Committee has only fragmentary and incomplete data covering the costs to railroads as a whole of constructing, operating and maintaining bridges crossing navigable waterways, but it is obvious that such expense is very large. It is also obvious that such expense is large to states, counties, and other local governmental sub-divisions. It is also a well-known fact that in many instances large expenditures have been and are required where the benefits to waterway traffic are negligible.

The cost of the construction, maintenance and operation of bridges over navigable waterways in the United States is fixed by the provisions of the Statutes of the United States pertaining to navigation and navigable waters. Section 491 of Chapter 11—Bridges Over Navigable Waters—reads as follows:

"Approval of and deviation from plans. When, after March 23, 1906 authority is granted by Congress to any persons to construct and maintain a bridge across or over any of the navigable waters of the United States, such bridge shall not be built or commenced until the plans and specifications for its construction, together with such drawings of the proposed construction and such map of the proposed location as may be required for a full understanding of the subject, have been submitted to the Secretary of War and Chief of Engineers for their approval, nor until they shall have approved such plans and specifications and the location of such bridge and accessory works, and when the plans for any bridge to be constructed under the provisions of this chapter, Section 491 to 498, inclusive, have been approved by the Chief of Engineers and by the Secretary of War it shall not be lawful to deviate from such plans, either before or after completion of the structure, unless the modification of such plans has previously been submitted to and received the approval of the Chief of Engineers and of the Secretary of War."

Section 494 of Chapter 11—Bridges Over Navigable Waters—reads as follows:

"Obstruction of navigation; alterations and removals; lights and signals; draws; tolls. No bridge erected or maintained under the provisions of this chapter, Sections 491 to 498, inclusive, shall at any time unreasonably obstruct the free navigation of the waters over which it is constructed, and if any bridge erected in accordance with the provisions of this chapter, Sections 491 to 498, inclusive, shall, in the opinion of the Secretary of War, at any time unreasonably obstruct such navigation, either on account of insufficient height, width of span, or otherwise, or if there be difficulty in passing the draw opening or the drawspan of such bridge by rafts, steamboats or other water craft, it shall be the duty of the Secretary of War, after giving the parties interested reasonable opportunity to be heard, to notify the persons owning or controlling such bridge to so alter the same as to render navigation through or under it reasonably free, easy, and unobstructed, stating in such notice the changes required to be made, and prescribing in each case a reasonable time in which to make such changes, and if at the end of the time so specified the changes so required have not been made, the persons owning or controlling such bridge shall be deemed guilty of a violation of this chapter, Sections 491 to 498, inclusive; and all such alterations shall be made and all such obstructions shall be removed at the expense of the persons owning or operating said bridge. The persons owning or operating any such bridge shall maintain, at their own expense, such lights and other signals thereon as the Secretary of Commerce shall prescribe. If the bridge shall be constructed with a draw, then the draw shall be opened promptly by the persons owning or operating such bridge upon reasonable signal for the passage of boats and other water craft. If tolls shall be charged for the transit over any bridge constructed under the provisions of this chapter, sections 491 to 498, inclusive, of engines, cars, street cars, wagons, carriages, vehicles, animals, foot passengers, or other passengers, such tolls shall be reasonable and just, and the Secretary of War may, at any time, and from time to time, prescribe the reasonable rates of toll for such transit over such bridge, and the rates so prescribed shall be the legal rates and shall be the rates demanded and received for such transit."

The provisions of the statutes are based on the theory that there is an inalienable right inherent in the use of a waterway and that all forms of land transportation must be subordinate to it. In other words, facilities required by all forms of land transportation in crossing a navigable waterway must be provided at the sole cost and expense of the owners thereof, and must conform to any changes made thereafter in the waterway itself or in the waterway traffic.

For the purpose of this report, navigable waterways will be considered in three subdivisions, as follows:

1. Waterways in their natural condition.
2. Natural waterways which are improved by deepening, widening, straightening, or otherwise, or on which the character of waterway traffic is changed by improvements made elsewhere, or by changes in design of vessels or methods of waterway transportation.
3. Artificial waterways.

It seems clear to your Committee that the provisions of the Statutes of the United States now in force are based on an erroneous principle. The principle may have been proper in the early period of this country's existence when waterways were the principal avenues of transportation, but that time is long since past. For many years the inland waterways of the United States have borne but a negligible part of the total inland transportation. The highways and railroads are the main agencies of inland transportation, and true public interest demands that the harbor transportation agencies should not be penalized by being subordinate to a minor agency. Our laws should be modelled on the principle of the greatest good to the largest number and on fairness and equity to all.

In many cases streams originally narrow and shallow, on which only canoes or other small craft could navigate, have been deepened, widened and straightened from time to time so that the entire character of the stream and the navigation thereon has been completely changed. In other cases, the uses of streams have been radically changed by changing connecting channels or by the removal of obstructions elsewhere, or by change in design of vessels or methods of water transportation. In other cases, artificial channels have been constructed, sometimes for purposes other than navigation, which since have been improved for navigation or the character of waterway traffic changed. In some cases, the waterway is changed by constructing locks and dams which raises the water level, causing changes not only in bridges but resulting in damage to other forms of property. Under the present United States laws, the expense of conforming bridges and collateral facilities to meet the changes made in the navigable streams are required to be borne by the owners of those facilities.

Most of the improvements to navigable streams are made for the purpose of providing new or improved waterways for navigation purposes. This navigation usually competes with other forms of transportation. A waterway project should be undertaken only if the total expenditure required to construct, maintain and operate it can be economically justified. It should not be undertaken if only a part of the expenditure (that part now commonly borne by the Federal government) can be economically justified, the remainder of the expenditure to be borne by private interests or some local governmental sub-division.

Your Committee is of the opinion that the following principles are equitable and should govern in providing funds for the construction, maintenance and operation of bridges, including approaches thereto, over navigable waterways:

1. Any agency providing facilities for land transportation when bridging a navigable waterway in its natural state, an improved waterway, or an artificial waterway, should assume the expense (but not more than) of constructing, maintaining and operating the bridge and other collateral facilities reasonably necessary to permit the use of such waterway in its condition at the time the crossing is made.

2. Where an artificial waterway is constructed across existing land transportation routes, the governmental authority in charge of and providing the funds for the waterway project should bear the entire expense of constructing, maintaining and operating bridges and other collateral facilities required on account of such crossing, not only as originally made, but all changes or alterations made thereafter on account of changes in the waterway or the character of traffic on such waterway.

3. When a waterway is improved by widening, straightening, deepening or otherwise, or the character of traffic on the waterway is changed by improvements elsewhere, or by changes in the design of vessels using the waterway, or by changes in methods of waterway transportation, which require changes in the bridges or other collateral facilities carrying land transportation agencies over such waterway, the governmental authority in charge of and providing the funds for the waterway should bear the expense of making such changes in the bridges or other collateral facilities, and the additional expense of maintaining and operating such altered bridges or facilities over and above the expense of the maintenance and operation of the bridges and facilities as they existed before such changes were made.

4. Any agency providing facilities for land transportation, crossing a navigable waterway, requiring, for its own purposes, changes in the bridges carrying it over the waterway, its collateral facilities, or in the waterway itself, the land transportation agency should bear the expense of making such changes, and the additional expense of maintaining and operating such altered bridges or facilities over and above the expense of the maintenance and operation of the bridges and facilities as they existed before such changes were made.

Waterways are only one of several means of inland transportation and it is to the public interest that all of these agencies should bear the expense properly applicable to the providing of the facilities necessary for such transportation agency, and the maintenance and operating expenses properly attributable to it. If this is not done it results in discrimination and the penalizing of one form of transportation to the benefit of some other form. Inasmuch as they are all competing agencies there should be no discrimination.

Therefore, it is the conclusion of your Committee that a change should be made in the present Statutes of the United States to bring about an allocation of the expense of construction, maintenance and operation of bridges over navigable waterways in accordance with the principles herein set forth.

## REPORT OF SPECIAL COMMITTEE ON WATERPROOFING OF RAILWAY STRUCTURES

J. A. LAHMER, *Chairman*;  
G. E. BOYD,  
O. F. DALSTROM,  
HUGO FILIPPI,  
L. V. HAEGERT,  
A. C. IRWIN,

F. R. JUDD,  
A. H. MORRILL,  
G. A. RODMAN,  
I. L. SIMMONS,  
F. P. TURNER,

G. A. HAGGANDER, *Vice-  
Chairman*;  
L. W. WALTER,  
H. T. WELTY,  
C. A. WHIPPLE,  
*Committee.*

*To the American Railway Engineering Association:*

Your Committee presents herewith its report on the following subjects:

- (1) Revision of Manual. Nothing to report.
- (2) When to waterproof or dampproof and methods to be used (Appendix A).
- (3) Waterproofing and dampproofing as applied to existing railway structures. Nothing to report.
- (4) Specifications for membrane waterproofing (Appendix B). These specifications are substantially the same as those which were submitted as information a year ago and printed in Bulletin 350. Some minor changes have been made for purpose of simplification and a few to eliminate inconsistencies.

### Action Recommended

- (2) That the report in Appendix A be received as information.
- (4) That specifications in Appendix B be adopted as recommended practice and published in the Manual in place of specifications on pages 1171 to 1180.

Respectfully Submitted,

SPECIAL COMMITTEE ON WATERPROOFING OF RAILWAY STRUCTURES,  
J. A. LAHMER, *Chairman.*

### Appendix A

#### (2) WHEN TO WATERPROOF OR DAMPPROOF AND METHODS TO BE USED

O. F. Dalstrom, Chairman, Sub-Committee; L. V. Haegert, A. C. Irwin, G. A. Rodman, I. L. Simmons, C. A. Whipple.

For convenience, the following definitions of waterproofing and dampproofing are quoted from A.R.E.A. Bulletin 347, "Revisions and Additions to the Manual" (July, 1932):

**WATERPROOFING.**—The treatment of any material or structure to prevent the entrance or passage of water or other liquid under head.

**DAMPPROOFING.**—The treatment of any material or structure to prevent the entrance or passage of water or other liquid not under head.

## PRINCIPLES GOVERNING THE USE OF WATERPROOFING OR DAMPPROOFING OF RAILWAY STRUCTURES

### Waterproofing

1. Adequate and effective drainage should be provided to remove water from the waterproofed surface if practicable.

2. Where the range of temperature varies from above freezing to below freezing, the disintegrating effect of frost action on water-saturated masonry must be recognized and adequately guarded against.

Where the temperature does not fall below freezing, the destructive effects of water penetration, but not permeation, are small. In cases of the passage of small quantities of water through parts of structures not subject to freezing temperatures, waterproofing should be provided only as required by appearance of surfaces or use of structure.

3. Waterproofing should not be applied to the face of masonry subject to freezing and thawing, where water reaches that face through the masonry.

4. The materials for waterproofing and the methods of application should be such as to insure that the waterproofing will be retained by bond, anchorage or other adequate means, in its original position as applied to the surface to be waterproofed.

5. Where waterproofing is subject to possible injury from abrasion, pressure, puncture or otherwise, it should be protected with a substantial covering.

6. Waterproofing should be applied where economically justified, considering the use and probable life of the structure and the cost of obtaining adequate watertightness by design and construction.

7. The type of waterproofing should be determined by the use and probable life of the structure, and the cost of renewal of the waterproofing:

(A) Waterproofing of the most durable and effective type should be used on permanent structures:

(a) In locations subject to water or other liquids under a hydrostatic head.

(b) Where repair or renewal is impracticable or prohibitive in cost.

(c) Where certainty of watertightness must be had because of heavy damage if water enters.

(B) Waterproofing specially designed for the purpose should be used where the structure must be protected against liquids containing corrosive and/or disintegrating substances.

8. A waterproofing membrane on the surface adjacent to the water source is the most effective externally applied waterproofing, but difficulties of application and prohibitive cost may sometimes make consideration of some other method advisable.

9. Surface applications on the inner faces of walls for the purpose of waterproofing against external pressure must derive their effectiveness from bond with the masonry or from closing the surface pores. Such applications can generally be considered effective only to prevent seepage under little or no head. Such coatings must be insoluble and unaffected by dampness.

### Dampproofing

1. Dampproofing is effective in preventing the accumulation of surface moisture from condensation only in proportion to its temperature-insulating value.

2. Dampproofing will probably not be effective where masonry is subject to moisture saturation accompanied by cycles of freezing and thawing.

3. Ordinary dampproofing is not effective against cracks or openings through the masonry.

4. A frequent fault of one-coat dampproofing is failure to produce a continuous covering free from pin holes. This should be considered in deciding upon the number of coats that should be applied.

5. The purpose and character of dampproofing are not such as to require special protection or covering. Where protection or covering is necessary, the conditions will usually warrant the use of waterproofing.

6. A prime requisite of dampproof covering is that it shall stay in place. Bond with the surface is therefore essential.

7. The selection of materials for dampproofing must include consideration of the effect of extremes of temperature, the effect of the sun's rays, and the physical and chemical effects of the liquid to which they will be subjected.

#### SPECIFIC CASES

##### Abutments, Piers and Retaining Walls

1. On the assumption that effective drainage has been provided, waterproofing on the back of an abutment or retaining wall is generally not necessary, but dampproofing should be provided above the footings. Where it is desired to prevent the passage of water, expansion joints and construction joints should be sealed by metal dams or other effective means.

##### Single-Span Arches and Box Culverts

2. Single-span arches and box culverts should be dampproofed on the surfaces in contact with the fill.

##### Pedestrian Subways

3. Pedestrian subways should be waterproofed.

##### Arches—Multiple Span with Spandrel Fill

4. Arches of multiple span with spandrel fill should be fully waterproofed on all surfaces in contact with the fill, including the parapets.

##### Precast Slabs for Bridge Decks and Floors

5. (A) Not over Streets or Pedestrian Subways—

- (a) The top surface of slabs and the backs of parapets should be damp-proofed when used on reinforced concrete pile bents with cast-in-place reinforced concrete caps, or on concrete piers.
- (b) The top surface of slabs and the backs of parapets should be damp-proofed when set on steel floorbeams, stringers or girders.

Joints should be calked with oakum up to within 2 or 3 inches of tops of slabs, the calking extending downward as far as necessary to close the joints against the flow of the waterproofing material used to fill the joints. The space above this oakum packing shall then be filled to the top surface of the slab with plastic joint-filling material.

(B) Over Streets or Pedestrian Subways—

In addition to treatment of joints as in paragraph (b) next above, the top surface of slabs and the backs of parapets should be waterproofed.

##### Cast-In-Place Concrete Bridge Decks or Floors

- 6. (a) The top surface of slabs and the backs of parapets should be damp-proofed and the construction joints closed with metal dams, where the slab is an integral part of the structure, as in rigid frames or girderless flat slabs, or where it is the main load-carrying element, as in simple or continuous slabs, provided it is sufficiently reinforced for both positive and negative moments.

- (b) When the slab is not a main load-carrying member, but is reinforced for temperature only and is supported on steel beams, all construction joints should be closed with metal dams and membrane waterproofing applied.

### **Pump Pits for Subways and Basements**

7. Pump pits should be waterproofed or dampproofed on all exterior surfaces.

### **Pipe Manholes and Pipe Tunnels**

8. Pipe manholes and pipe tunnels in water-bearing soils should be dampproofed or waterproofed on all exterior surfaces.

### **Water Containers**

9. The walls and floors of water containers, such as reservoirs and tanks, should be made of dense concrete to insure watertightness. Special attention should be given to the waterproofing of all joints.

### **Walls and Floors of Buildings**

10. The walls and floors of all buildings subject to hydrostatic pressure should be waterproofed on exterior and under surfaces.

If not subject to hydrostatic pressure, all exterior walls should be dampproofed. Special attention should be given to all joints and to places where pipes or other facilities pass through walls.

### **Grain Elevator Pits and Similar Underground Structures**

11. Grain elevator pits and similar underground structures should be made watertight by design and construction or waterproofed on the exterior.

## **Appendix B**

### **(4) SPECIFICATIONS FOR MEMBRANE WATERPROOFING**

#### **Scope**

1. These specifications are intended to apply to materials and methods for waterproofing bridge decks, backs of abutments and retaining walls, tops and backs of culverts, subways, tunnels, conduits, foundations for buildings, walls and floors of basements and pits, tanks, reservoirs, dams and any other masonry structure or part of such structure, except roofs of buildings.

#### **Design**

2. Structures to be waterproofed shall be so designed that they can be waterproofed by the methods and with the materials specified herein. When the structure to be waterproofed is flexible and supported at intervals on comparatively rigid supports, such as cross girders in a viaduct, special care shall be taken to provide flexibility in the waterproofing membrane over such supports. Care shall also be taken to seal effectively or flash all places where the waterproofing membrane terminates, as along the webs of girders.

The waterproofing shall consist of a membrane covered by a protection of brick, concrete, mastic or other material.

## Types

3. The membrane shall consist of one of the following types:

- (a) Two layers of bitumen-treated cotton fabric and three moppings of bitumen.
- (b) Three layers of bitumen-treated cotton fabric and four moppings of bitumen.
- (c) Two layers of bitumen-treated felt, one middle layer of bitumen-treated cotton fabric, and four moppings of bitumen.
- (d) Four layers of bitumen-treated felt, one middle layer of bitumen-treated cotton fabric, and six moppings of bitumen.

When greater strength is required, additional layers of bitumen-treated cotton fabric shall be applied.

## MATERIALS

### Bitumen

4. Bitumen shall consist of asphalt or coal-tar pitch. The mopped-on material shall be the same type of bitumen as that with which the felt or fabric is treated.

### Asphalt for Saturant and Mopping Above Ground

5. Asphalt for saturant and mopping above ground shall be homogeneous and free from water. It shall be the product obtained by the distillation of crude asphaltic base petroleum with steam agitation, supplemented if necessary with oxidation by air, but without the addition, during any stage of the process of manufacture, of any fluxing material other than a native asphalt or a straight steam refined asphaltic residual. It shall meet the following requirements:

- (a) Softening point (ring and ball method).....150° to 170° Fahr. (65.5° to 76.7° C.)
- (b) Penetration: at 115° Fahr. (46.1° C.), 50 g., 5 sec.....not more than 100  
at 77° Fahr. (25° C.), 100 g., 5 sec.....25 to 40  
at 32° Fahr. ( 0° C.), 200 g., 60 sec.....not less than 10
- (c) Flash point (open cup).....not less than 400° Fahr. (204.4° C.)
- (d) Loss on heating at 325° Fahr. (163° C.), 50 g., 5 hr.....
- (e) Penetration at 77° Fahr. (25° C.), 100 g., 5 sec. of residue after heating at 325° Fahr. (163° C.), as compared with penetration of asphalt before heating.....not more than 0.5 per cent
- (f) Ductility: at 77° Fahr. (25° C.) elongated at rate of 5 cm. per min.  
.....not less than 20 cm.
- (g) Ductility: at 40° Fahr. ( 4° C.) elongated at rate of 1 cm. per min.  
.....not less than 4 cm.
- (h) Solubility in carbon disulphide.....not less than 99 per cent

### Asphalt for Mopping Below Ground

6. Asphalt for mopping below ground shall be either (a) a native refined asphalt fluxed with a petroleum flux, this flux to have a penetration at 77 degrees Fahr. of not less than 350 under a weight of 50 grams for one second; or (b) a petroleum asphalt obtained as a residue of an asphaltic petroleum by straight steam-refining without oxidation. It shall be free from admixtures of blown or oxidized residuals, cracked residuals, sludge asphalt, or their derivatives. It shall have the following properties:

|                                                      | <i>Fluxed Native Asphalt</i> | <i>Petroleum Asphalt</i> |
|------------------------------------------------------|------------------------------|--------------------------|
| (a) Specific gravity at 60° Fahr....                 | 1.04 to 1.07                 | 1.03 to 1.06             |
| (b) Penetration at 77° Fahr., 100 grams, 5 sec. .... | 85 to 100                    | 85 to 100                |
| (c) Softening point (ring and ball method) .....     | 110° to 125° Fahr.           | 110° to 125° Fahr.       |

|                                                                                                                                                   | <i>Fluxed Native Asphalt</i> | <i>Petroleum Asphalt</i> |
|---------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|--------------------------|
| (d) Ductility of pure bitumen at 77° Fahr. (25° C.) elongated at rate of 5 cm. per min.....                                                       | Min. 100 c.m.                | Min. 100 c.m.            |
| (e) Flash point.....                                                                                                                              | 350° Fahr. to 450° Fahr.     | Min. 450° Fahr.          |
| (f) Loss on heating.....                                                                                                                          | Max. 2.0%                    | Max. 1.0%                |
| (g) Penetration at 77° Fahr., 100 g., 5 sec., of residue after heating at 325° Fahr. as compared with penetration of asphalt before heating ..... | Min. 60%                     | Min. 60%                 |
| (h) Pure bitumen soluble in carbon disulfide .....                                                                                                | Min. 95%                     | Min. 99½%                |
| (i) Inorganic matter, insoluble ....                                                                                                              | Min. 1½%                     | ...                      |
| (j) Paraffine scale (Holde method)                                                                                                                | Max. ½%                      | ...                      |

### Coal-Tar Pitch for Saturant and Mopping

7. Coal-tar pitch for saturant and mopping shall be homogeneous and free from water. It shall meet the following requirements:

|                                                                                                       | <i>For Use Above Ground</i> | <i>For Use Below Ground</i> |
|-------------------------------------------------------------------------------------------------------|-----------------------------|-----------------------------|
| (a) Specific Gravity at 77°/77° Fahr. (25°/25° C.).....                                               | 1.25 to 1.35                | 1.21 to 1.30                |
| (b) Softening point (cube in water method) .....                                                      | 130° to 155° Fahr.          | 110° to 140° Fahr.          |
| (c) Distillation Test:                                                                                |                             |                             |
| Total distillate by weight 32° to 572° Fahr. (0 to 300° C.).....                                      | Max. 10%                    | Max. 15%                    |
| Residue by weight.....                                                                                | Min. 90%                    | Min. 85%                    |
| (d) Specific gravity, at 100°/77° Fahr. (38°/25° C.) of total distillate to 572° Fahr. (300° C.)..... | Min. 1.03                   | Min. 1.03                   |
| (e) Ductility at 77° Fahr. (25° C.)...                                                                | Min. 20 cm.                 | Min. 50 cm.                 |
| (f) Solubility in carbon disulphide....                                                               | 63% to 78%                  | 75% to 90%                  |

### Asphaltic Primer

8. Asphaltic primer shall be composed of asphalt that conforms to the foregoing requirements for asphalt for mopping below ground, and a solvent. It shall meet the following requirements:

|                                                               |                           |
|---------------------------------------------------------------|---------------------------|
| (a) Water .....                                               | None                      |
| (b) Asphaltic Base:                                           |                           |
| Per cent asphalt is of primer by weight....                   | 30 to 45                  |
| (c) Solvent (Hydrocarbon distillate):                         |                           |
| End point on distillation.....                                | Max. 500° Fahr. (260° C.) |
| Per cent which shall distill under 248° Fahr. (120° C.) ..... | Max. 20                   |
| (d) Sediment .....                                            | Max. 1%                   |

### Creosote Primer

9. Creosote primer for use with coal-tar pitch shall conform to the following requirements:

|                                                     |                |
|-----------------------------------------------------|----------------|
| (a) Water .....                                     | Max. 2.0%      |
| (b) Consistency at 100° Fahr. (38° C.).....         | Entirely fluid |
| (c) Specific gravity at 100°/77° Fahr. (38°/25° C.) | 1.00 to 1.06   |
| (d) Insoluble in benzol .....                       | Max. 1.0%      |

- (e) Distillation Test:
  - Total distillate, by weight, under 392° Fahr. (200° C.) ..... Max. 5.0%
  - Total distillate, by weight, under 455° Fahr. (235° C.) ..... Max. 50.0% Min. 30.0%
- (f) Residue, by weight, above 671° Fahr. (355° C.) ..... Max. 15.0%
- (g) Specific gravity at 100°/77° Fahr. (38°/25° C.) of the fraction distilling between 455° and 599° Fahr. (235° C. and 315° C.) ..... Min. 1.00
- (h) Consistency at 77° Fahr. (25° C.) of the residue Soft

## Fabric

10. Fabric shall consist of high-grade cotton cloth saturated thoroughly and uniformly with asphalt or coal-tar pitch for use above ground, which conforms to the foregoing specifications.

11. In the process of manufacture, the dry cotton fabric shall be treated thoroughly and uniformly at a temperature and speed that will not injure the fabric. This shall be accomplished by passing the fabric through the saturant and then calendering it in the presence of heat, after which it shall be cooled and wound into rolls.

## Untreated Fabric

- 12. Untreated fabric shall contain no oil. It shall meet the following requirements:
  - (a) Thread count in either direction: Minimum 18; maximum 32.
  - (b) Average weight per square yard: For cloth having 18 to 24 thread count, not less than 5 ounces including not to exceed 6 per cent moisture regain; for cloth having 26 to 32 thread count, not less than 4 ounces including not to exceed 6 per cent moisture regain.
  - (c) Ash: Not more than one per cent of dry weight of fabric.

## Treated Fabric

- 13. Treated fabric shall meet the following requirements:
  - (a) Width of roll: Minimum 30 in.; maximum 38 in.
  - (b) Gross weight of roll: Minimum 35 lb.; maximum 80 lb.
  - (c) Average weight per square yard: Not less than 11 ounces for 4 oz. cloth and 13¾ oz. for 5 oz. cloth.
  - (d) Moisture content: Not more than one per cent of net weight.
  - (e) Tensile strength at 70° Fahr. in either direction (grab method): Not less than 50 lb. per linear inch.
  - (f) Elongation without fracture: Not less than 10%.
  - (g) Pliability at 32° Fahr.: Not less than 10.
  - (h) Average loss on heating asphalt treated fabric (exclusive of moisture): Not more than 4 per cent.
  - (i) Weight of saturant in square yard of treated fabric: Not less than one and three-fourths times the weight of a square yard of untreated moisture-free fabric.

14. There shall be sufficient space between the threads of the untreated cotton fabric to allow the saturant to pass through. The surface of the saturated fabric shall be smooth and free from folds, knots and excess saturant.

## Felt

15. Felt shall be rag-felt saturated, but not coated, with either asphalt or refined coal-tar; or asbestos felt saturated, but not coated, with asphalt. Rag felt shall be produced by felting vegetable and animal fibers.

16. Saturation shall be accomplished by passing the dry felt in single thickness through the saturant at a temperature and speed that will not injure the felt, and then calendering it between heated cylinders. It shall then be cooled and wound into rolls.

17. Rag felt shall meet the following requirements:

#### DESATURATED

|                                                | <i>Asphalt Saturated</i>     | <i>Coal Tar Saturated</i>    |
|------------------------------------------------|------------------------------|------------------------------|
| (a) Average weight of moisture-free felt ..... | Min. 5.2 lb. per 100 sq. ft. | Min. 5.2 lb. per 100 sq. ft. |
| (b) Ash in moisture-free felt .....            | Max. 10%                     | Max. 10%                     |

| Distillate, per cent by weight to 235° C. calculated on extracted saturant .....     |                                                                                                       | Max. 5                                                                                                |
| (g) Pliability at 77° Fahr. (25° C.)                                                 | At least four strips out of five shall not crack when bent thru 180° over a $\frac{1}{8}$ in. mandrel | At least four strips out of five shall not crack when bent thru 180° over a $\frac{1}{8}$ in. mandrel |
| (h) Saturant in moisture-free felt, by weight .....                                  | Min. 140%                                                                                             | Min. 140%                                                                                             |

18. Asbestos felt shall meet the following requirements:

#### DESATURATED

- (a) Average thickness ..... not less than 0.045 in.
- (b) The relative proportion of the organic and asbestos fibers based on a microscopic count:
  - Organic ..... not more than 10%
  - Asbestos and hair..... not less than 90%
- (c) The felt shall contain cattle hair uniformly distributed. The amount of cattle hair shall be from 10 to 15 per cent, by weight, of the asbestos fiber content.

#### SATURATED

- (a) Width of roll..... 32 to 36 in.  $\pm \frac{1}{4}$  in.
- (b) Gross weight of roll..... 48-80 lb.
- (c) Weight of material per 100 sq. ft. exclusive of wrapping and packing..... 30 lb.  $\pm$  1½ lb.
- (d) Loss on heating at 221° Fahr. (105° C.) for 5 hrs..... not more than 4%
- (e) Moisture content..... not more than ½% of net weight
- (f) Weight of saturant, not less than 55% of the weight of moisture free felt.
- (g) Mullen test to show a strength of 45 lb. minimum and 55 lb. maximum at 70° Fahr. (21° C.)

19. The surface of the felt shall be uniformly smooth, and upon splitting or tearing on the bias, shall appear reasonably free from lumps of underbeaten stock, i.e., stock

that has not been beaten or shredded into fiber in the process of manufacture, and from particles of foreign substance, such as fragments of stone, metal, leather, rubber, straw, wood, etc.

20. Felt shall be saturated thoroughly and uniformly and shall show no unsaturated spots at any point upon cutting 2-in. strips at random across the entire sheet and splitting them open for their full length.

21. Finished cotton fabric or felt shall be free from visible defects, such as holes, ragged or untrue edges, breaks, rents or cracks, and shall not be coated or covered with talc or other substance that will interfere with adhesion between the fabric or felt and the bitumen.

22. Saturated fabric shall be wound on mandrels not less than 2 in. in diameter and extending from 2 to 4 in. beyond the ends of the roll. Saturated felt need not be wound on cores.

23. Rolls of cotton fabric or felt shall be wrapped securely or tied to prevent unrolling in transit. It shall be of such quality that it may be unrolled easily at atmospheric temperatures above 50 degrees Fahr. without injury from sticking.

24. Cotton fabric, felt, asphalt and coal-tar pitch shall be delivered on the work in the original packages bearing the manufacturer's brand or label. The kind of material and the purpose for which it is to be used shall be indicated on the label.

### Insulating Paper

25. Insulating paper shall be a waterproof paper 36 in. wide, weighing not less than 10 lb. per 100 sq. ft.

### Plastic Cement

26. Plastic cement shall be composed of semi-solid asphalt dissolved in a suitable volatile solvent and stiffened with a mineral filler consisting essentially of short fiber asbestos.

27. The asphalt forming the base of plastic cement shall be either a fluxed native asphalt or a straight steam-refined asphaltic petroleum residual that has not been oxidized or blown, the pure bitumen of which shall meet the following minimum requirements:

|                                                 |          |
|-------------------------------------------------|----------|
| Penetration at 77° Fahr., 100 grams, 5 sec..... | 30       |
| Ductility at 77° Fahr., 5 c.m. per min. ....    | 100 c.m. |

It shall be free from water, oxidized petroleum, residuals from the cracking process, sludge asphalt, tar or pitch products, or derivatives thereof.

28. Plastic cement shall meet the following requirements:

#### *By Weight*

|                                                                       |             |
|-----------------------------------------------------------------------|-------------|
| Fluxed Native or Steam-refined Petroleum Asphalt, not less than ..... | 38 per cent |
| Short Fiber Asbestos, not less than.....                              | 25 " "      |
| Petroleum Solvent, not more than.....                                 | 25 " "      |

29. Plastic cement shall be of such consistency that it can be spread readily with a trowel without drawing or pulling, or can be extruded through a suitable nozzle under a pressure of 50 lb. or more per sq. in.

30. When applied in a layer  $\frac{1}{8}$  to  $\frac{1}{2}$  in. thick, plastic cement shall set within 24 hours to a tough plastic coating, free from blisters.

31. After drying for 72 hours, a patch of plastic cement  $\frac{1}{8}$  to  $\frac{1}{2}$  in. thick, applied to the material upon which it is to be used, shall not blister or sag more than  $\frac{1}{4}$  in. upon exposure at a temperature of 140 degrees Fahr. for five hours.

32. After drying for 72 hours, and exposure at a temperature of 140 degrees Fahr. for 5 hours, a patch of the cement  $\frac{1}{8}$  to  $\frac{1}{4}$  in. thick shall be plastic and adhere well to saturated fabric, saturated felt, metal or concrete, upon exposure at a temperature of 32 degrees Fahr. for one hour.

33. After drying for 24 hours and exposure at a temperature of 140 degrees Fahr. for 24 hours, and then cooling to a temperature of 70 to 77 degrees Fahr., a patch of the cement  $\frac{1}{8}$  to  $\frac{1}{4}$  in. thick shall not crack or break from the saturated fabric, saturated felt or metal, when bent over a mandrel 1 in. in diameter.

### Asphalt Mastic

34. Asphalt mastic shall be used in the form of premoulded blocks or shall be poured in place. Poured-in-place mastic shall be composed of (a) asphalt mixed with mineral aggregates, or (b) mastic cake mixed with asphalt and mineral aggregates.

### Asphalt for Mastic

35. Asphalt for mastic shall be homogeneous and free from water. It shall meet the following requirements:

|                                               |                                    |
|-----------------------------------------------|------------------------------------|
| Penetration: at 77° Fahr. (25° C.), 100 g.,   |                                    |
| 5 sec. ....                                   | 25 to 30                           |
| Flash point (open cup).....                   | not less than 347° Fahr. (175° C.) |
| Loss on heating at 325° Fahr. (163° C.),      |                                    |
| 50 g., 5 hr.....                              | not more than 2 per cent           |
| Penetration at 77° Fahr. (25° C.), 100 g.,    |                                    |
| 5 sec. of residue after heating at 325° Fahr. |                                    |
| (163° C.), as compared with penetration of    |                                    |
| asphalt before heating.....                   | not less than 60 per cent          |
| Ductility at 77° Fahr. (25° C.).....          | not less than 15 cm.               |
| Proportion of bitumen soluble in carbon       |                                    |
| tetrachloride .....                           | not less than 99 per cent          |

NOTE.—When less than 99 per cent of asphalt is soluble in carbon tetrachloride, the per cent of bitumen (solubility in carbon disulphide) shall be reported.

### Coarse Mineral Aggregate

36. Coarse mineral aggregate shall be well-graded crushed stone or washed gravel that will pass a  $\frac{3}{8}$ -in. screen and be retained on a No. 10 screen. It shall be free from soft particles and organic matter.

### Fine Mineral Aggregate

37. Fine mineral aggregate shall be well graded washed sand or crushed stone that will pass a No. 10 screen. It shall be free from soft particles and organic matter.

### Mineral Filler

38. Mineral filler shall be finely ground limestone or silica meeting the following requirements:

|                               |                            |
|-------------------------------|----------------------------|
| Passing a 200-mesh sieve..... | not less than 75 per cent  |
| Passing a 30-mesh sieve.....  | not less than 100 per cent |

### Portland Cement

39. Portland cement shall meet the requirements of the Standard Specifications for Portland Cement of the American Railway Engineering Association, or current revisions thereof.

### Mastic Cake

40. Mastic cake shall contain from 14 to 18 per cent, by weight, of matter soluble in pure benzol. The soluble matter shall be asphalt that will meet the requirements of

Section 35. The insoluble matter other than that inherently present in the asphalt used, shall be granular mineral matter that will meet the requirements of sections 37 and 38.

### Premoulded Asphalt Blocks

41. Premoulded asphalt blocks shall meet the following requirements:

They shall be 4 in. wide, 8 in. long, and  $1\frac{1}{4}$  in. thick. A deviation of  $\frac{1}{4}$ -in. in length or  $\frac{1}{8}$ -in. in width or thickness either way from these dimensions, shall be cause for rejection.

The blocks shall be formed in moulds, under a pressure of not less than 3300 lb. per sq. in. of surface. An absorption test shall be made on blocks dried for 24 hours at a temperature of 150° Fahr. (65.5° C.) and then immersed in water seven days. The absorption of moisture under this test shall not exceed 1 per cent of the weight of the block.

### Asphalt Plank

42. Asphalt plank shall be a mixture of asphalt, mineral matter and organic fiber, but not wood fiber. It shall be not less than  $1\frac{1}{4}$ -in. thick, and shall weigh not less than 85 lb. per cu. ft. The average of three tests shall show the following proportions by weight:

Asphalt (by Soxhlet extraction apparatus): Min. 40%; max. 48%; average 42.5%.

Mineral matter (measured as ash): between 35% and 45%.

Organic fiber, etc. (sum of asphalt and ash subtracted from 100): 8% to 22%.

The per cent of ash shall not exceed the percentage of asphalt.

43. From each shipment ten finished planks shall be selected at random, five for penetration and five for impact tests. One specimen shall be cut from each plank. If more than one specimen from each group fails to meet the requirements of the respective tests, the shipment will be rejected.

(a) The specimens for the penetration test shall be 6 in. by 6 in. They shall be kept at a temperature of 140 degrees Fahr. for  $1\frac{1}{2}$  hours immediately preceding the test. The test shall be made by placing the specimen under a freely moving plunger 1 in. in diameter, actuating a micrometer gage. The end of the plunger that is in contact with the specimen shall be convex with a radius of curvature of 2 in. A weight of 56 lb. shall be placed on the plunger and readings on the gage shall be taken 15 sec. and 75 sec. after the weight has been applied. The difference of these readings shall be the penetration of the specimen. To meet the requirements of this test, the penetration shall not exceed 0.03 in.

(b) The specimens for the impact test shall be 2 in. in diameter. They shall be kept at a temperature of 32 degrees Fahr. for 2 hours immediately preceding the test. The test shall be made by placing the specimen under a plunger 1 in. in diameter, which shall be seated exactly on center with the specimen. The end of the plunger that is in contact with the specimen shall be a plane surface perpendicular to the axis of the plunger. After the plunger is seated, a weight of 10 lb. shall be dropped on it from a height of 15 in. To meet the requirements of this test the specimen shall neither fracture nor crack.

44. The asphalt plank shall be of uniform width and thickness with sides straight and all edges square. The thickness, width and length, and details of bends shall be as shown on the plans. Curb and gutter plank shall be extruded in final shape from a mold. Irregularly formed planks shall be crated for shipment.

Asphalt plank shall be so loaded as to avoid deformation by irregular supports. The load shall be blocked, if necessary, to prevent shifting while in transit.

## Materials for Concrete

45. Materials for concrete shall meet the requirements of the American Railway Engineering Association's current specifications for concrete. Reinforcing shall be steel wire netting with a mesh not less than 2 in. The wire shall be No. 14 gage or heavier.

## Brick

46. Brick shall not be less than  $2\frac{1}{4}$  in. thick with square corners, and shall be free from warp. It shall be dense, hard burned, and uniform in size and quality. The absorption of moisture by bricks immersed in water seven hours shall not exceed 10 per cent of the weight of the dry brick.

## INSPECTION AND TESTS

47. Except as otherwise provided, materials shall be sampled and tested for the specified properties by the current methods recommended by the American Society for Testing Materials.

48. The acceptance of any materials by the Inspector shall not be a bar to their subsequent rejection if found defective. Rejected materials shall be replaced promptly by the manufacturer.

49. All materials to be furnished by the Contractor shall be delivered on the work not less than three weeks before they are to be applied, in order that they may be tested and analyzed. No materials shall be used until they have been accepted by the Engineer.

## APPLICATION

50. Membrane waterproofing shall not be applied in wet weather, or when the atmospheric temperature is below 50 degrees Fahr. without written permission of the Engineer. The waterproofing shall be free from punctures, pockets or folds.

51. Surfaces to be waterproofed shall be dry and clean. Projections that might injure the membrane shall be removed. There shall be no depressions or pockets in horizontal surfaces of finished waterproofing. Concrete shall be well cured before waterproofing is applied.

52. The waterproofing shall be turned without break into drainage castings. Special care shall be taken to make the waterproofing effective along the sides and ends of girders and at stiffeners, gussets, etc. Grooves shall be filled with plastic cement specified in Sections 26 to 33, inclusive.

53. On surfaces that are vertical or nearly so, the strips of cotton fabric or felt shall be laid vertical or with the slope; on other surfaces the strips shall be laid shingle fashion, beginning at the lowest part of the surface to be waterproofed. Sufficient cotton fabric or felt shall be allowed for suitable lap or anchorage at the upper edge of the surface to be waterproofed.

54. Surfaces of concrete or steel coming in contact with asphalt waterproofing shall be given one coat of asphaltic primer before the first mopping of asphalt, or one coat of creosote primer before the first mopping of coal-tar pitch, except where insulation is to be used at expansion joints. The primer shall be well worked in to give a uniform coating. The priming coat shall be applied approximately 24 hours before applying the waterproofing membrane and shall be dry before the first mopping is applied.

55. Surfaces to be waterproofed shall be mopped in sections. While the first mopping of bitumen is still hot, a strip of cotton fabric or felt shall be laid on the mopping and pressed into place. Each mopping thereafter shall be so applied that it will com-

pletely cover and seal the cotton fabric or felt. The amount of bitumen used for each mopping shall be not less than  $4\frac{1}{2}$  gal. for each 100 sq. ft. of surface.

56. Asphalt shall not be heated above a temperature of 350 degrees Fahr., and coal-tar pitch not above 250 degrees Fahr. The bitumen shall be stirred frequently while being heated. Kettles shall be equipped with armored thermometers.

57. Two-ply work shall be started by mopping a section of the surface 2 in. wider than half the width of the cotton fabric or felt. On this hot mopping a half-width of the cotton fabric or felt shall be laid. The top surface of this cotton fabric or felt and an adjacent section of the surface 2 in. wider than a half-width of the cotton fabric or felt shall then be mopped. On this mopping shall be laid a full width of the cotton fabric or felt, completely covering the first strip. Thereafter full widths of cotton fabric or felt shall be laid in hot moppings, and in such manner that each strip will lap the second preceding strip by 2 in. Side laps shall be not less than 2 in. and end laps not less than 12 in.

58. The procedure for 3-ply work shall be the same as for 2-ply work, except that the first strip shall be a one-third width of the cotton fabric or felt; the second strip a two-thirds width; and the third and succeeding strips, full widths. The second full strip shall lap the first strip at least 2 in. Each succeeding strip shall lap the third preceding strip at least 2 in.

Membrane waterproofing consisting of more than three plies shall be built up in shingle fashion similar to 3-ply work by addition of as many plies as required.

59. The work shall be so regulated that at the end of the day all fabric or felt that has been laid will have received the final coat of bitumen.

60. Patching shall not be done without permission from the Engineer. Where patching is permitted for defective waterproofing it shall extend at least 12 in. beyond the outermost edge of the defective portion. The second and each succeeding ply of the patch shall extend at least 3 in. beyond the preceding ply.

61. At construction joints the primer shall be omitted for a width of 18 in. of the surface and a strip of insulating paper laid thereon before waterproofing is applied.

62. Expansion joints shall be filled with plastic cement conforming to these specifications. Joints shall be dry and clean immediately before they are filled. They shall be over-filled slightly to allow for shrinkage in drying.

### Protective Cover

63. The protective cover shall be placed as soon as practicable after the membrane has been laid. Dirt and other foreign material shall be removed from the surface of the membrane immediately before the protective cover is placed. One of the following methods of protection shall be employed:

- (a) A layer of poured-in-place asphalt mastic not less than  $1\frac{1}{2}$  in. thick.
- (b) A layer of asphalt blocks not less than  $1\frac{1}{4}$  in. thick or a layer of asphalt plank not less than  $1\frac{1}{4}$  in. thick, laid in an extra heavy mopping of asphalt, with joints filled with hot asphalt.
- (c) A layer of adequately reinforced cement mortar or concrete not less than 2 in. thick.
- (d) A course of hard burned brick not less than  $2\frac{1}{4}$  in. thick with joints filled with hot asphalt except that when laid as a vertical wall or on a steep slope, bricks shall be laid in cement mortar.

NOTE.—Mastic shall not be used on surfaces steeper than  $4\frac{1}{2}$  vertical to 12 horizontal. A protective cover containing asphalt shall be placed on only a membrane in which the bitumen used is asphalt.

64. Poured-in-place mastic shall be laid on one thickness of insulating paper placed on the membrane. It shall be made as specified in Sections 65 or 66.

65. The asphalt and mineral aggregates shall be mixed in the following proportions, varied within the specified limits, to give a mastic of the greatest density and stability:

|                                                                                   |                   |
|-----------------------------------------------------------------------------------|-------------------|
| Asphalt meeting requirements of section 35.....                                   | 9 to 12 per cent  |
| Coarse mineral aggregate meeting requirements of section 36....                   | 33 to 40 per cent |
| Fine mineral aggregate meeting requirements of section 37.....                    | 33 to 37 per cent |
| Mineral filler or Portland cement meeting requirements of sections 38 or 39 ..... | 15 to 19 per cent |

66. Mastic cake, asphalt and mineral aggregates shall be mixed in approximately the following proportions, varied to give a mastic of the greatest density and stability:

|                                                                                                                     |             |
|---------------------------------------------------------------------------------------------------------------------|-------------|
| Mastic cake meeting requirements of section 40.....                                                                 | 48 per cent |
| Asphalt meeting requirements of section 35.....                                                                     | 5 per cent  |
| Coarse mineral aggregate meeting requirements of section 36.....                                                    | 28 per cent |
| Fine mineral aggregate, and mineral filler or Portland cement meeting requirements of sections 37 and 38 or 39..... | 19 per cent |

67. The asphalt and mastic cake shall be heated together to a temperature not above 350 degrees Fahr. The aggregates shall be mixed and heated and then placed in the kettle of melted asphalt. The ingredients shall be well-mixed with iron stirring rods until all pieces of the aggregate are covered with asphalt and the aggregates distributed uniformly throughout the mixture. During the mixing process care shall be taken to avoid burning the asphalt. After the mastic has been mixed it shall be poured into place while hot. It shall be placed in layers not more than  $\frac{3}{4}$ -in. thick. The thickness shall be gaged by wooden strips held in position by suitable weights. The layers shall be brought to the required thickness with wooden spreaders and floats, and shall lap joints not less than 6 in. The top layer shall be finished to the required grade and to a smooth surface. As soon as the top layer of the mastic is finished, it shall be given a mopping of hot asphalt sanded to a walking surface while hot.

68. Premoulded block protection shall be laid over the entire membrane except around drainage castings and other places shown on the plans. In such places, poured-in-place mastic or concrete shall be used. The blocks shall be laid in hot asphalt and the joints filled immediately with hot asphalt.

69. Asphalt plank protection shall be laid in hot asphalt. The asphalt shall be applied not less than 50 lb. to the square (100 sq. ft.) and the placing of the plank shall follow immediately. As successive planks are laid, the edges and ends of adjacent planks already laid shall be coated heavily with hot asphalt. The planks shall be laid tight against those previously laid so that the asphalt will completely fill the joints and be squeezed out at the top. After all planks have been laid, any joints not completely filled shall be filled with hot asphalt.

70. Concrete protection shall be not less than 2 in. thick and shall be reinforced as shown on the plans. The concrete shall be as dry as consistent with the workability required. It shall contain  $1\frac{3}{4}$  barrels of cement per cubic yard of concrete.

71. Unless otherwise permitted by the Engineer, traffic shall not be allowed on the concrete until that deposited last has had the equivalent of seven days of good curing.

### Brick Protection Course

72. Brick protection shall be laid over the entire membrane, except around drainage castings and at other places shown on the plans. In such places concrete shall be used. The joints between bricks shall be filled immediately after the bricks have been laid, with hot bitumen of the kind used for saturant and mopping, except that when against a vertical wall or on a steep slope the brick shall be laid in cement mortar.

## REPORT OF COMMITTEE XVII—WOOD PRESERVATION

|                                   |                 |                                    |

|                                   |                 | <i>Committee.</i>                  |

### *To the American Railway Engineering Association:*

Your Committee respectfully presents herewith reports covering the following subjects:

- (1) Revision of Manual (Appendix A).
- (2) Service Test Records for Treated Ties (Appendix B).
- (3) Piling used for Marine Construction (Appendix C).
- (4) Specifications for Treatment of Air-Seasoned Douglas fir, collaborating with Committees III—Ties and VII—Wooden Bridges and Trestles (Appendix D).
- (5) Destruction by Termites and possible ways of Prevention (Appendix D).
- (6) Loss of Preservative in Treated Ties in Track due to use of Oil-burning Weed Destroyers, collaborating with Committee XIII—Water Service and Sanitation, XXII—Economics of Railway Labor and XXVII—Maintenance of Work Equipment (Appendix F).
- (7) Methods of Protection of Treated Materials in the Field, collaborating with Committees III—Ties and VII—Wooden Bridges and Trestles (Appendix G).
- (8) Service Test Records of Structural Timber, including piling (Appendix H).

### **Action Recommended**

1. That the information contained in Appendix A—Revision of Manual, Appendix D, Specifications for Treatment of Air-seasoned Douglas Fir, and the conclusions noted in Appendix H—Service Test Records of Structural Timber, be approved for publication in the Manual.
2. That the information contained in Appendix B—Service Test Records for Treated Ties; Appendix C—Piling Used in Marine Construction, and Appendix E—Destruction by Termite and possible ways of Prevention, be accepted as information.
3. That the information contained in Appendix F—Loss of Preservative in Treated Ties in Track due to repeated Use of Oil-burning Weed Destroyers, and Appendix H—Service Test Records of Structural Timber, including Piling, other than the conclusions reached, be accepted as information and the subjects discontinued.
4. That the information contained in Appendix G—Methods of Protection of Treated Materials in the Field—be received as information and the subject continued, with the recommendation to the Committee on Outline of Work that collaboration of Committees—III—Ties; VII—Wooden Bridges and Trestles, and XVII—Wood Preservation be directed with Committee XII—Rules and Organization to the end that approved rules be published in the Manual under the jurisdiction of Committee XII.

Respectfully submitted,

THE COMMITTEE ON WOOD PRESERVATION,

F. C. SHEPHERD, *Chairman.*

## Appendix A

## (1) REVISION OF MANUAL

O. C. Steinmayer, Chairman, Sub-Committee; E. B. Fulks, R. S. Belcher, C. S. Burt, Walter Buchler, C. W. Greene, M. F. Jaeger, H. E. Horrocks, F. D. Mattos, G. C. Stephenson, L. B. Shipley, Dr. Hermann von Schrenk.

## (A) PROPOSED SPECIFICATION FOR CREOSOTE

During recent years, committees representing the American Railway Engineering Association, the American Wood Preservers' Association and the American Society for Testing Materials, concerned with wood preservation, have been attempting to harmonize the creosote specifications of the various associations in order to eliminate a certain amount of confusion which has existed. This has been accomplished, practically, on the part of the American Wood Preservers' Association and the American Society for Testing Materials.

The present specifications of the American Wood Preservers' Association for Creosote and Creosote-Coal Tar Solution are very satisfactory, and are used very widely throughout the wood preserving industry. Your Committee believes that it would be advantageous to bring our specifications into harmony with those of the American Wood Preservers' Association. This will involve a change in the clauses relating to the specific gravity of fractions and the addition of two footnotes, and a renumbering of the various paragraphs.

The specific gravity requirements of the fractions 235–315°C. and 315–355°C. were inserted originally to prevent the addition to creosote of water-gas tar, but that situation no longer exists for the reason that water-gas tar has established a market for itself and is sold readily without resorting to subterfuge. On the other hand, changes have taken place in the production of coal tar which have changed the character of the tar itself. In the early days, the principal sources of coal tar were gas works or old-style coke ovens, both of which were operated at high temperatures and the tars produced were thick, viscous and of high specific gravity. Now, by far the larger proportion of tar comes from coke ovens which have been greatly improved in design, construction and method of operation and which produce thin tars having comparatively low specific gravities. This results in the production of considerable quantities of perfectly good coal-tar creosote which does not meet the requirements of 1.03 and 1.10 for specific gravity of fractions. We have collected the analyses of a great many creosotes which fall in this class and which represent a large volume of production. A few of them are presented as an illustration:

*Specific Gravity at 38°C.*

|         | <i>Oil</i> | <i>235</i> | <i>315</i> |
|---------|------------|------------|------------|
|         |            | <i>315</i> | <i>355</i> |
| A ..... | 1.058      | 1.028      | 1.092      |
| B ..... | 1.086      | 1.027      | 1.093      |
| C ..... | 1.064      | 1.028      | 1.092      |
| D ..... | 1.055      | 1.026      | 1.090      |
| E ..... | 1.075      | 1.022      | 1.097      |
| F ..... | 1.065      | 1.024      | 1.091      |
| G ..... | 1.059      | 1.030      | 1.096      |
| H ..... | 1.079      | 1.030      | 1.095      |
| I ..... | 1.082      | 1.028      | 1.100      |
| J ..... | 1.053      | 1.025      | 1.088      |
| K ..... | 1.061      | 1.026      | 1.100      |
| L ..... | 1.065      | 1.029      | 1.099      |

The determining of the specific gravities of the fractions 235–315 and 315–355°C. has been found useful in connection with other analytical factors in determining whether the creosote is a pure coal tar product. In view of the changes in tar production, it is felt, however, that the figures now given in clause five of the present specification should be lowered. The specific gravity of the fraction between 235 and 315°C. is usually not lower than 1.025 and the specific gravity of the fraction between 315 and 355°C. is not usually lower than 1.085, both taken at 38°C. compared with water at 15.5°C. In their last revision of the creosote specification, the American Wood Preservers' Association, recognizing this fact, incorporated the clause just quoted as a part of a footnote. Your Committee feels that an identical footnote should be added to the revised specification for creosote oil which we are recommending.

In addition to this clause, your Committee also recommends that two other clauses adopted by the American Wood Preservers' Association as a part of the footnote dealing with two additional characteristics of the fractions of creosote be adopted by this Association in the identical form as that appearing in the American Wood Preservers' Association Manual.

Your Committee also recommends that a second footnote be appended to the revised American Railway Engineering Association specification similar to number two now part of the standard American Wood Preservers' Association specification. This deals with the interpretation of the clause dealing with the amount insoluble in benzol. Creosotes are frequently rejected because the quantity of insoluble is found to be slightly in excess of the specified quantity. It has been found that this is frequently due to the increase of insoluble matter due to treating operations.

The Manual now contains specifications for three grades of creosote which are of the same general character, the difference being that those for grades two and three provide for creosotes which are lighter and more volatile than grade one. These were written "to be used when the higher grade oil cannot be procured" and, presumably, these creosotes would be cheaper than grade one creosote. This situation no longer exists. There is now an ample supply of grade one creosote and only small quantities of grades two and three are manufactured. In fact, if a purchaser should desire to procure a large amount of either of these grades, he probably could not do so, or if he succeeded, it would be at a higher price than that of grade one. Since specifications for grades two and three no longer are pertinent, it would seem that they might well be discontinued. We are advised that the American Wood Preservers' Association is considering taking similar action.

The recommendations made with reference to changes in the present specification for grade one creosote are intended to apply equally to the present specification for 80/20 creosote coal tar solution.

Your Committee therefore recommends that the Manual be revised as follows:

1. Withdraw the specifications, shown on pages 1286, 1287 and 1288, Manual of 1929, for Creosote, Grade One; Creosote, Grade Two; Creosote, Grade Three; and Creosote-Coal Tar Solution.

2. Approve the following specifications for:

(A) CREOSOTE—AMERICAN RAILWAY ENGINEERING ASSOCIATION

STANDARD SPECIFICATIONS FOR CREOSOTE—GRADE ONE

1. The creosote shall be a distillate of coal-gas tar or coke-oven tar (see Note 1). It shall comply with the following requirements:
2. It shall not contain more than 3 per cent water.

3. It shall not contain more than 0.5 per cent of matter insoluble in benzol (see Note 2).
4. The specific gravity of the creosote at 38°C., compared with water at 15.5°C. shall be not less than 1.03.
5. The distillate, based on water-free creosote, shall be within the following limits:  
Up to 210°C. not more than 5 per cent.  
Up to 235°C. not more than 25 per cent.
6. The residue above 355°C., if it exceeds 5 per cent, shall have a float test of not more than 50 seconds at 70°C.
7. The creosote shall yield not more than 2 per cent of coke residue.
8. The foregoing tests shall be made in accordance with the standard methods of the American Railway Engineering Association.

#### NOTES

NOTE 1.—Owing to the complexity of the chemical composition and physical properties of coal-tar creosote, and to the fact that some of the same compounds and properties which characterize coal-tar creosote are found in certain petroleum derivatives, the determination of the purity of creosote is difficult. When there is not certain assurance that the creosote is a pure product, the following tests will aid in arriving at an opinion as to its coal-tar origin:

(a) Fraction distilling between 210°C. and 235°C. is usually solid or contains some solids when cooled to 25°C.

(b) All of the fractions up to 315°C. contain tar acids in varying amounts usually at least 1 per cent, calculated on the amount of the fraction tested.

(c) The specific gravity of the fraction between 235°C. and 315°C. is usually not lower than 1.025 and specific gravity of the fraction between 315° and 355° is usually not lower than 1.085 at 38°C. compared with water at 15.5°C. However, some pure coal-tar distillates fall slightly below these limits.

If the creosote does not comply with at least one of the foregoing tests, it is undoubtedly not a pure coal-tar creosote.

NOTE 2.—Samples of creosote taken from working tanks may show an increase in matter insoluble in benzol due to treating operations. Such increases, provided they do not exceed by 1 per cent the specification limits, should not serve to cause rejection of the creosote for non-conformity with specifications, if it can be shown that the original fresh creosote was of specified quality.

#### (B) CREOSOTE COAL-TAR SOLUTION—AMERICAN RAILWAY ENGINEERING ASSOCIATION

##### STANDARD SPECIFICATIONS FOR CREOSOTE COAL-TAR SOLUTION

1. The solution shall be a coal-tar product of which at least 80 per cent shall be a distillate of coal-gas tar or coke-oven tar, and the remainder shall be refined or filtered coal-gas tar or coke-oven tar (see Note 1). It shall comply with the following requirements:
  2. It shall not contain more than 3 per cent of water.
  3. It shall not contain more than 2 per cent of matter insoluble in benzol (see Note 2).
  4. The specific gravity of the solution at 38°C. compared with water at 15.5°C. shall be not less than 1.05 or more than 1.12.
  5. The distillate, based on water-free creosote shall be within the following limits:  
Up to 210°C. not more than 5 per cent  
Up to 235°C. not more than 25 per cent
  6. The residue above 355°C., if it exceeds 26 per cent shall have a float-test of not more than 50 seconds at 70°C.

7. The solution shall yield not more than 6 per cent coke residue.
8. The foregoing tests shall be made in accordance with the standard methods of the American Railway Engineering Association.

#### NOTES

NOTE 1.—Owing to the complexity of the chemical composition and physical properties of coal-tar creosote, and to the fact that some of the same compounds and properties which characterize coal-tar creosote are found in certain petroleum derivatives, the determination of the purity of creosote is difficult. When there is not certain assurance that the creosote is a pure product, the following tests will aid in arriving at an opinion as to its coal tar origin:

(a) Fraction distilling between 210°C. and 235°C. is usually solid or contains some solids when cooled to 25°C.

(b) All of the fractions up to 315°C. contain tar acids in varying amounts usually at least 1 per cent, calculated on the amount of the fraction tested.

(c) The specific gravity of the fraction between 235°C. and 315°C. is usually not lower than 1.025 and specific gravity of the fraction between 315° and 355° is usually not lower than 1.085 at 38°C. compared with water at 15.5°C. However, some pure coal tar distillates fall slightly below these limits.

If the creosote does not comply with at least one of the foregoing tests, it is undoubtedly not a pure coal-tar creosote.

NOTE 2.—Samples of solution taken from working tanks may show an increase in matter insoluble in benzol due to treating operations. Such increases provided they do not exceed by 1 per cent the specification limits, should not serve to cause rejection of the solution for non-conformity with specifications, if it can be shown the original fresh solution was of specified quality.

### (C) STANDARD METHODS FOR THE DETERMINATION OF TAR ACIDS IN CREOSOTE

The American Railway Engineering Association, at the present time, has adopted methods for measuring, sampling and analyzing preservatives, which are printed in the Manual. There is one method, however, which has not yet been presented or recommended for adoption, namely the Standard Methods for Determination of Tar Acids in Creosote. Your Committee therefore presents such methods with the recommendation that they be approved as standard practice for inclusion in the Manual. The methods herewith recommended are the same as those included in the manual of recommended practices of the American Wood Preservers' Association. Both of these methods have been used and practiced for a great many years.

### STANDARD METHODS FOR THE DETERMINATION OF TAR ACIDS IN CREOSOTE

#### *Contraction Method*

**Apparatus.**—Tar-acid separatory funnel, Type 1 (see Fig. 1). Tar-acid separatory funnel, Type 2 (see Fig. 2).

#### *Distillation Method*

**Method.**—100 c. c. of oil shall be placed in a distilling apparatus such as is used in distillation test and distilled until at least 95 per cent of distillate has been obtained or until the vapor temperature has reached 400°C. The entire distillate shall be transferred to a tar-acid separatory funnel, Type 1, designed for oils which have 25 per cent or over tar acids, or Type 2 for oils containing less than this amount. The funnel with the creosote shall be placed in a water bath and kept at a constant temperature of 60°C. until no change in volume takes place. It shall then be extracted with successive

portions of 50 c. c. each of 10 per cent caustic soda solution until no further diminution in volume occurs. The soda shall be added to the oil, the whole thoroughly shaken, then returned to the bath at 60°C. and allowed to settle completely. After settling is complete, the soda layer shall be drawn off and the volume of residual oil noted. When the point of no further contraction is reached, the diminution in volume of the oil shall be considered as tar acids.\*

This test is recommended for all general work in oil specifications and general comparative tests, but gives results slightly higher than the true tar-acid content of the oil. The reason for this is that soda withdraws from creosote oil certain compounds which are not subsequently liberated from the soda solution in the form of an oil. These substances are evidently acid in nature but not phenolic bodies.

#### *Liberation Method*

**Apparatus.**—Same as above. Water and tar separatory funnel (see Fig. 2, J. Eng. and Ind. Chem. vol. 10 [1918], 735).

**Method.**—100 c. c. of oil shall be distilled as described above.

(Where the content of tar acids is very low, a distillation may be made on 200 c.c. so as to obtain a more accurate test.) The oil shall be shaken in a separatory funnel with successive 50 c.c. portions of 10 per cent caustic soda or until no more tar acids are removed. The well-settled separated carbolate shall be acidified in a small beaker with 40 per cent sulphuric acid, taking care to keep the mixture cool at all times. (If the content of tar acids is under 5 per cent, use the water in tar separatory funnel and measure carefully into it 10 c.c. of "Hiflash" naphtha. The liberated tar acids and sulphate solution are then poured through this layer of naphtha several times, drawing the material off at the bottom of the funnel into the original beaker and pouring it back into the top of the funnel. This washes out the beaker and allows all the tar acids to be absorbed by the naphtha.) The funnel shall then be allowed to stand until the layers separate perfectly clearly, when the sulphate solution shall be drawn off and the increase in volume of the naphtha taken as the dry tar acids present. When the content of acids is over 5 per cent the same procedure can be used, measuring 65 c.c. of "Hiflash" naphtha into the tar-acid separatory funnel, Type 2.

**Precaution.**—All results must be figured on the basis of dry oil.

Your Committee recommends the adoption of the above described Specification for Standard Methods for the Determination of Tar Acids in Creosote for publication in the Manual.

\* In some cases (such as creosote-tar solutions containing small amounts of acids) there will be insufficient material to bring the oil up into the graduated section of Type 2 separatory funnel. In such cases, sufficient tar-acid free, clean, heavy naphtha may be added to dilute the oil and bring it within the graduated portion.

FIG. 1—Tar-Acid Separator Funnel, Type 1.

FIG. 2—Tar-Acid Separator Funnel, Type 2.

### Appendix B

#### (2) SERVICE TEST RECORDS FOR TREATED TIES

W. R. Goodwin, Chairman, Sub-Committee; Z. M. Briggs, C. S. Burt, E. A. Craft, C. W. Greene, L. B. Holt, R. S. Hubley, R. P. Hughes, A. J. Loom, F. C. Krell, G. P. MacLaren, T. H. Strate.

The table of tie renewals per miles maintained on the various railroads has been revised to include renewals for 1932.

Reports are submitted covering special test tracks on the following lines:

Chicago, Burlington & Quincy.  
St. Louis Southwestern.  
Chicago and Northwestern.  
Chicago, Milwaukee, & St. Paul.  
Atchison, Topeka, and Santa Fe.

### Conclusion

Your Committee recommends that this report be accepted as information.

CHICAGO, BURLINGTON & QUINCY RAILROAD

<sup>a</sup> Rail cutting, splitting, etc. <sup>b</sup> Western Washington and Oregon type. <sup>c</sup> Switch ties - average life 6.5 years.

Condition of experimental ties in the Chicago, Milwaukee, St. Paul and Pacific Railway test track near Hartford, Wis., after about 21-3/4 years service (Continued)

[illegible]

Small cutting, splitting, etc.  
Obtained from regular stock of C.M.St. P. & P. Ry.  
5% zinc chloride solution  
Emulsion of 80 parts of 3% zinc chloride solution and 20 parts of creosote by volume at approximately 70°F.  
5% zinc chloride solution plus creosote. Treatment consisted of bath in hot creosote for 30 minutes at atmospheric pressure followed by pressure treatment with 3% zinc chloride solution.  
5% zinc chloride solution  
Heatproof treatment in cold mercuric chloride solution. Absorption figures not available.

STATEMENT SHOWING VARIOUS SPECIAL TESTS FOR THE AMERICAN RAILWAY ENGINEERING ASSOCIATION  
AS OF DECEMBER 31, 1932  
A. T. & S. F. RY.

## Appendix C

## (3) PILING USED FOR MARINE CONSTRUCTION

Wm. G. Atwood, Chairman, Sub-Committee; G. B. Campbell, C. C. Cook, H. R. Condon, L. H. Harper, G. R. Hopkins, H. E. Horrocks, G. C. Stephenson, C. M. Taylor.

## Conclusion

Your Committee recommends that this report be accepted as information.

The Committee submits herewith its report on the present condition of the long-time test pieces under its observation, together with such other pertinent information as has come to its knowledge.

## Tropical Timber

ANGELIQUE OR BASRALOCUS (*Dicorynia paraensis*, Benth)

Submerged September 13, 1923. Balboa, C.Z. There was considerable marine growth and the limnoria damage, while not very deep, was general on all surfaces. The pholads were plentiful, confined as usual close to the surfaces. The same was true of the teredoes which were all very small, few in number. The timber is in very good condition otherwise.

MANBARKLAK (*Lecythis ollaria*, L.) Submerged Balboa, C.Z. September 13, 1923.

There was considerable marine growth on the surfaces. In general the timber appeared to be very sound. A section was cut from the end (Fig. 1). In this were eight *Martesia* and six *Xylophaga*. Teredoes were very few, very small, less than  $\frac{1}{8}$  inch in diameter, and limited very close to the surfaces, especially the ends. The wood was very hard and in excellent condition.

GREENHEART (*Nectanda rodiei*, Schomb). Submerged Balboa, C.Z. September 13, 1923.

There was much marine growth and a fair number of pholads. A section was cut. In it were a number of pholads and plenty of teredoes, some  $\frac{3}{8}$ -inch in diameter, but the wood was not yet over-riddled by them. They show no difficulty in working through the wood. Many were dead with silt in the burrows. Otherwise the wood is sound.

## GREENHEART.—From Panama Canal Stock. Submerged Balboa, C.Z. September 26, 1931.

One side was clean, the other had much marine growth. There were quite a number of pholad and teredo holes. A 3 inch section was cut from the end. It had many pholads and teredoes were plentiful some  $\frac{5}{8}$  inch in diameter. A few were dead.

3, 4, Manbarklak, (1613) (Zetek)  
(FIG. 1)

GREENHEART.—Yellow Heart. Submerged Balboa, C.Z. July 18, 1932.

There was much marine growth and a few pholads. *Teredo* appeared to be few, small and apparently confined close to the surfaces. Timber in good condition.

GREENHEART.—Dark Brown Heart. Submerged Balboa, C.Z. July 18, 1932.

There was much marine growth and some mud. *Teredo* appear to be few in number, small and close to the surfaces. Timber in good condition.

GREENHEART.—Light Brown Heart. Same as above.

TURPENTINE WOOD (*Syncarpia laurifolia*). U. S. District Engineer, Charleston, S. C.

Submerged at Castle Pinckney, S.C. June 24, 1925. Specimen attacked by *teredo* on the ends and surface. The remainder of the specimen is solid. About 60 per cent of the useful material still remains.

Panama Canal. Submerged Balboa, C.Z. April 19, 1929.

There is much marine growth and very many pholad cavities. Last August a section was cut from the ends of both specimens and this year there are several new pholads in the cut end. *Teredo* are fairly plentiful, confined close to the surfaces and all relatively small. The timber is very sound.

#### PANAMA CANAL

Through the courtesy of Lt. Col. Julian L. Schley, Governor of the Panama Canal Zone, we are able to present the following report on tests being made at Balboa.

"I have to advise that the inspection was performed by Mr. James Zetek on August 7th, and under date of August 21st he has submitted the following report with the attached photographs.

"This report covers examination of timbers in the *teredo* resistance tests at Balboa, Canal Zone, made by me on August 7, 1933.

"Wherever marine growth is mentioned, it includes ascidians, bryozoans, sponges, 'worms', etc., as well as such other encrusting forms as oysters (including *Anomia peruviana*), *Vermetidae* (mollusks), the brachiopod *Disciniscia cumingii*, etc. At least forty species of mollusks were found, those of *Crepidula*, *Crucibulum*, *Anomia* and *Ostrea* being the most abundant.

"Unless limnoria is mentioned, it was either absent or else its work was negligible.

"The two pholads, *Martesia* and *Xylophaga*, are the same species referred to in previous reports. In some timbers these were far more destructive than the *teredo*. They were especially abundant in Red Satinway (No. 1624-21) which test was closed out largely because of them.

"The principal *teredo* found was *Neobankia zeteki* Bartsch. In only one case was *Teredora panamensis* Bartsch found.

"Most of the untreated timbers that show a high resistance to *teredos*, are very hard, heavy, and difficult to work. Some have a twisted grain, and Kolaka' (No. 1637)

was almost impossible to split with a sharp axe. Wherever it is indicated that the wood was sound, or in excellent condition, it means just that, except for the parts damaged by pholads or teredos."

#### (A) UNTREATED TIMBERS

"MALABAYABAS, Philippine Islands, No. 1606-9; 12"  $\times$  12"  $\times$  13"; submerged September 13, 1923. This wood is very heavy. A section 1½" thick was cut from the end. There was much marine growth on the surfaces and a large number of *Martesia* and *Xylophaga* openings. In the section cut were about 60 of these pholads, but teredos very very few in number, small, and entirely confined very close to the surface. Teredo work was negligible. The wood is very hard and sound, but it splits rather easily because of the even grain.

"SPONSE HOEDOE (*Licania macrophylla Benth*), from Dutch Guiana, No. 1610-5; 8"  $\times$  8"  $\times$  24", submerged September 13, 1923. There was little marine growth, gribble damage not severe but more than last year. The sides show many openings of the two pholads. Last year a section was cut from the end. Another section was cut this year. In this section were about 80 pholads. Many of these were dead, and there was mud and silt in the cavities. Teredos were few in number, small, confined close to the surfaces, especially the end. Most of these were dead, with mud and silt in the burrows. The wood is very hard, with twisted grain, and very sound.

KAJOL LARA (*Metrosideros sp.*), from the Celebes, No. 1615-11; 6½"  $\times$  6½"  $\times$  30", submerged October 26, 1925. Very little marine growth. Much mud present. A section was cut from the end. Very few pholads were present. Teredos were few, very small, confined to area ⅜" from the end. Very little gribble work. The wood was very hard and in excellent condition.

FOENGO (*Parinarium campestre Aubl.*), from Dutch Guiana, No. 1608-4; 8"  $\times$  8"  $\times$  24", submerged September 13, 1923. There was considerable marine growth and a fair amount of gribble damage. Last year a section was cut from the end, and another one was cut at this time. There were 8 *Martesia*, 12 *Xylophaga* and 1 *Lithrophaga* in this section. Teredos were plentiful, all small, ⅛ to ⅜ inch in diameter, not more than ¾ inch penetration. Some were dead. The wood is hard and very sound.

INGIEBARKI (*Licania heteromorpha Benth*), from Dutch Guiana, No. 1611-6; 6½"  $\times$  7"  $\times$  24", submerged September 13, 1923. There was much marine growth and the surfaces were badly damaged by gribble. A small section was cut from the end. It had about 40 pholads, all alive. There were many live teredos, small, some ⅜ inch in diameter, within 1" of the surfaces. The wood is very hard and except for the damage noted, in excellent shape.

RED SATINWAY, from New South Wales, No. 1624-21; 6"  $\times$  6"  $\times$  24", submerged April 19, 1929. There was an abundance of marine growth on all surfaces and a very large number of pholad cavities. Teredos were not numerous, confined rather close to surfaces. They were alive, some ⅝" in diameter. The wood otherwise was very sound and extremely difficult to split, very hard and with a twisted grain. It was almost impossible to dissect. CLOSED.

ANOURA (*Conepia Sp.*), from Dutch Guiana, No. 1609-2; 8"  $\times$  8"  $\times$  24"; submerged September 13, 1923. There was a fair amount of marine growth. Gribble damage was severe. Last year a section was cut from the end. Another was cut this time. In it were about 30 pholads, most of them dead, with much mud and silt in the cavities. One live *Lithophaga* was found. In addition to *N. zeteki*, *T. panamensis* was also present. The teredos were not numerous, all small, confined close to surfaces, penetration not over one inch from end. Most of these were dead, with mud in the burrows. Some were ⅜ inch in diameter, alive. The wood was very hard and in excellent condition.

KOLAKA, from the Celebes, No. 1637-13; 6"  $\times$  6"  $\times$  60"; submerged April 15, 1932. The surfaces were in fine shape with very little marine growth, and no gribble attack. No teredo holes were seen and a small section from the end showed nothing, not even pholads. Because of its size, the timber was cut in two and one piece will be used in teredo tests, the other in termite tests. The latter showed no indications of pholads or teredos. The wood is VERY hard and sound, the grain in places very much gnarled.

KAJOL MALAS (*Parastemon urophyllus*), from Sumatra, No. 1616-12; 6"  $\times$  6"  $\times$  30"; submerged October 26, 1925. This timber was resting on a concrete sill and it would appear that on August 9, 1932, with the tide high, when it was lowered into its place, it was allowed to rest on the sill instead of left to hang free. This means that each day at low tide it was not in water for a whole year. The marine growth was scant

but gribble damage was severe. There were a few pholad cavities. Teredos appeared to be in number, all small, otherwise the timber is in excellent condition.

ALAZANO (*Calcycophyllum candidissimum*) (Vahl DC.), from Panama, No. 1627-8; 6"  $\times$  6"  $\times$  30", submerged October 17, 1929. There was considerable marine growth. The surfaces show a large number of pholad cavities. Teredos are plentiful but the timber is still quite sound. The exact teredo picture was to be seen only in cut sections, as last August, and quite probably next August this test will have to be closed.

ALCORNQUE (*Dimorphandra mora* B. & H.), from Panama, No. 1617-14, all heart-wood; 6"  $\times$  6"  $\times$  53"; submerged November 22, 1927. Much marine growth on all sides and end. There are several pholad cavities. Teredos are not plentiful, are all small confined close to surfaces. Last August a 5" section was cut from the end. This year the cut end is very sound. The timber is in excellent condition.

BRUSH BOX, from New South Wales, No. 1625-22; 6"  $\times$  6"  $\times$  24"; submerged April 19, 1929. There was much marine growth. There appears to be more pholads than last time. Teredos are fairly plentiful, all small and close to the surfaces. The timber is very sound.

### (B) TREATED TIMBERS

AMARILLO (*Chlorophora tinctoria*), treated with A.R.E.A. No. 1 creosote; No. 1630-30; 9½"  $\times$  12½"  $\times$  9', one end scarfed after treatment; submerged September 20, 1930. The scarfing exposes wood with less treatment hence gives teredos a better chance to enter. Much marine growth. In general the timber is in excellent condition, but the scarfed surfaces show many holes. Similar holes, but not so many, are in the ends and sides. A two inch section was cut from the scarfed end, continuing the cut backward. This section shows the impregnation was not deep nor too good. In this small piece there were at least 40 teredos, most of them dead, some ⅜-inch in diameter.

PANAMA CANAL COPPER CEMENT TREATMENT. Seven tests, installed April 20, 1933. The treatment consists of 8 lb. ground copper cement, one gallon pine tar, as follows: heat the tar and stir into it the cement, dilute with gasoline till thin enough to apply cold. I understand it was suggested by J. H. Coleman of the Cia. Salitre de Chile, Valparaiso. For brevity, these tests are marked P.C. Cu Cement Paint. From my observations I do not think this treatment will amount to much. It is easily rubbed off and is too thin to last long.

P.C. Cu CEMENT PAINT, No. 1714-29, creosoted fir, P.C. stock, ends only coated with the paint, size 3"  $\times$  12"  $\times$  30". There was considerable marine growth and the wood seems to be sound. I did not cut into it.

P.C. Cu CEMENT PAINT, No. 1715-31, creosoted fir, P.C. stock, ends only coated with the paint, size 3"  $\times$  12"  $\times$  30". Same as preceding one.

P.C. Cu CEMENT PAINT, No. 1716-32, untreated fir, P.C. stock, coated all over with the paint, size 6"  $\times$  6"  $\times$  30". Much marine growth, the bivalve *Anomia peruviana* very plentiful. Apparently sound.

P.C. Cu CEMENT PAINT, No. 1717-33, untreated yellow pine, P.C. stock, coated all over with the paint. Size 6"  $\times$  6"  $\times$  30". Much marine growth. Apparently o.k.

P.C. Cu CEMENT PAINT, No. 1718-34, untreated almendra, P.C. stock, coated all over with the paint. Same as preceding one. 6"  $\times$  6"  $\times$  30".

P.C. Cu CEMENT PAINT, No. 1719-35, untreated greenheart, P.C. stock, coated all over with the paint, size 6"  $\times$  6"  $\times$  30". Same as preceding.

### (C) SPECIAL TEST

This is a special test installed January 19, 1933, consisting of a 2"  $\times$  12" plank of untreated fir, P.C. stock, to which were nailed 7 pieces of untreated fir, P.C. stock, 3½"  $\times$  3½"  $\times$  9". Each month, starting with February, one of these small blocks was removed and carefully examined. The object was to learn how fast teredos enter and work and to obtain material for study, especially valves and pallets. The blocks are referred to below by their age.

1 month,—surfaces show many small teredo openings. The inside was sound, and the teredos, about 20 in number, very very small, ⅛" and less in diameter, all alive, close to the surfaces.

2 months,—much like preceding except that there are more teredos, larger, ⅛" to ⅜" in diameter and more destruction. The center is not very bad. All teredos were alive.

3 months,—large number of live teredos, ¼" to ⅝" in diameter, even in the center of the block. Most destruction near the surfaces.

4 months,—great amount of teredos, ¼" to ⅜", all alive, wood well riddled throughout.

5 months,—much like preceding except that there were more teredos and the destruction is more pronounced. The surfaces, except for the number of tiny teredo openings, do not indicate condition within.

6 months,—very much like preceding one. Destruction greater.

7 months,—thoroughly riddled, practically finished, most of the teredos dead and most foul odor.

The  $2 \times 12$  plank,—completely riddled, most of the teredos dead, many very putrid, with most foul odor. Teredos  $\frac{3}{8}$ " to  $\frac{7}{16}$ " in diameter. A few pholads were in this plank.

This special test not only shows how fast teredos will work (though this is nothing new), but it served as a control, proving that teredos are present.

In the above report, as in previous reports, the identifying numbers of the specimens consist of two parts, namely, that before the dash indicating the Panama Canal test number, and that after the dash indicating the rack in which installed.

## CHEMICAL WARFARE SERVICE SPECIMENS

### SERIES No. 1

These test pieces were treated in 1924 and 1925 by the Chemical Warfare Service in their experimental plant at the Edgewood Arsenal. Treatment was with the following compounds:

No. 1. 1 per cent solution of ammoniacal copper carbonate.

No. 2. 1 per cent dyphenalamine chlorarsene in creosote.

No. 3. 0.75 per cent diphenylamine chlorarsene and 0.5 per cent phenyldichlorarsene in fuel oil.

#### No. 1 Treatments:

Test pieces at Charleston, S.C., Pensacola, Fla. have been practically destroyed, one piece at Coco Solo, C.Z. is very heavily attacked, but the other one much less.

San, Juan, P.R. Submerged 1925. Attacked by limnoria, slight teredo attack.

San Francisco Bay, Calif. Submerged July 21, 1925 at Oakland and Peralta St. Slip (moved from Port Costa). Both pieces show light to moderate limnoria attack.

Puget Sound Navy Yard. Submerged from Piers 4 and 8 in 1925. Both pieces heavily attacked by limnoria and Bankia and test discontinued.

#### No. 2 Treatments:

District Engineer, Charleston, S.C. Submerged at Castle Pinckney, June, 1925. One piece in good condition except for a few teredo holes, the other destroyed by teredo. Superintendent of Lighthouses, San Juan, P.R. Submerged 1925. In good condition. No evidence of attack.

U.S. Naval Air Station, Pensacola, Fla. Submerged July 8, 1925. One piece lost, the other shows moderate attack by limnoria on the ends.

U.S. Fleet Air Base, Coco Solo, C.Z. Submerged 1925. In very good condition, showing only a minor attack by limnoria around a knot.

Southern Pacific Company. Submerged June 1925. Light limnoria attack on both test pieces.

Puget Sound Navy Yard. Submerged November 1925. Both pieces hard and sound with no sign of borer attack.

## CHEMICAL WARFARE SERVICE

### SERIES No. 2

These test pieces were treated at the Edgewood Arsenal in 1931 with the following materials.

A A.R.E.A. No. 1 Creosote.

B A.R.E.A. No. 1 Creosote with 0.71 methylarsenious oxide.

C A.R.E.A. No. 1 Creosote with 0.77 diphenylamine chlorarsene.

D A.R.E.A. No. 1 Creosote with 2.5 dinitrophenol.

E Petroleum residuum with 2.5 per cent dinitrophenol.

F Petroleum residuum with 0.8 per cent methylarsenious oxide.

G Petroleum residuum with diphenylamine chlorarsene.

## Inspection reports follow:

**"A" TREATMENTS:**

Fort Tilden, N.Y. No attack except slight limnoria erosion on one end of one piece.  
Castle Pinckney, S.C. Slightly attacked by limnoria on ends.  
Naval Air Station, Pensacola, Fla. Slight limnoria attack on ends of both pieces.  
Balboa, C.Z. Apparently in good condition.  
Bureau of Lighthouses, San Juan, P.R. Good condition.  
Southern Pacific Co. Oakland Pier. Very light limnoria attack.  
Southern Pacific Co. Peralta Slip. No attack this year.  
Puget Sound Navy Yard. A few small Bankia holes in the end.  
Pearl Harbor Navy Yard. Light limnoria attack on both pieces.  
Cavite Naval Station. No report received.

**"B" TREATMENTS:**

Fort Tilden, N.Y. Very slight limnoria erosion on one end of one piece.  
Castle Pinckney, S.C. Light limnoria attack on sides and ends.  
Naval Air Station, Pensacola, Fla. Slight limnoria attack on end of one piece and a little heavier attack on the other.  
Balboa, C.Z. Apparently in excellent condition.  
Bureau of Lighthouses, San Juan, P.R. Good condition.  
Southern Pacific Company, Oakland Pier. Very light limnoria attack.  
Southern Pacific Company, Peralta Pier. Slight limnoria attack on one end.  
Puget Sound Navy Yard. Several Bankia holes in one piece, other piece more heavily attacked and discarded.  
Pearl Harbor, H.I. Navy Yard. Some limnoria attack on sides of one piece and about 20 holes in the other.  
Cavite Naval Station. Report not received.

**"C" TREATMENTS:**

Fort Tilden, N.Y. Very slight limnoria attack.  
Castle Pinckney, S.C. Slight limnoria attack.  
Naval Air Station, Pensacola, Fla. Slight limnoria attack on ends.  
Balboa, C.Z. Some limnoria attack. Several Martesia and Xylophaga, found in one end about 20 teredo, all dead.  
Supt. of Lighthouses, San Juan, P.R. Good condition.  
Southern Pacific Co. Oakland Pier. No attack.  
Southern Pacific Co. Peralta Pier. No attack.  
Puget Sound Navy Yard. A few Bankia entrance holes in the ends of both pieces.  
Pearl Harbor, H.I. Navy Yard. Both pieces lightly attacked by limnoria.  
Cavite, P.I. Naval Station. No report.

**"D" TREATMENTS:**

Fort Tilden, N.Y. Slight limnoria attack on one piece, none on the other.  
Castle Pinckney, S.C. Slightly attacked on ends by limnoria.  
Naval Air Station, Pensacola, Fla. No attack.  
Balboa, C.Z. Apparently in good condition.  
Supt. of Lighthouses, San Juan, P.R. Good condition.  
Southern Pacific Co. Oakland Pier. Very light limnoria attack.  
Southern Pacific Co. Peralta Pier. No attack.  
Puget Sound Navy Yard. Slight limnoria attack and a few Bankia entrance holes.  
Pearl Harbor, H.I. Navy Yard. One piece very lightly and one more heavily attacked by limnoria.  
Cavite, P.I. Naval Station. No report.

**"E" TREATMENTS:**

Fort Tilden, N.Y. One piece good, one with slight teredo attack.  
Castle Pinckney, S.C. Heavily attacked by teredo about one-half destroyed.  
Naval Air Station, Pensacola, Fla. One piece lost, other shows heavy attack by limnoria with some Martesia and teredo.  
Balboa, C.Z. Limnoria damage severe. Many pholad openings as well as teredo. A section was cut from the end. It had several pholads alive, some of the Martesia very large. There were about 90 teredo in this small section, most of them dead. Some were  $\frac{3}{8}$  inch in diameter. There was much petroleum residue in the holes.

Supt. of Lighthouses, San Juan, P.R. One piece in good condition, the other showing light limnoria and teredo attack.  
 Southern Pacific Co. Oakland Pier. No attack.  
 Southern Pacific Co. Peralta Pier. Very light limnoria attack.  
 Puget Sound Navy Yard. Pieces practically destroyed in first year.  
 Pearl Harbor, H.I. Navy Yard. Both pieces show moderate attack.  
 Cavite, P.I. Naval Station. No report.

**"F" TREATMENTS:**

Fort Tilden, N.Y. Very slight limnoria attack.  
 Castle Pinckney, S.C. Heavily attacked only about 65 per cent useful material remaining.  
 Naval Air Station, Pensacola, Fla. One piece half destroyed by limnoria, and also contains a few teredo. The other piece heavily attacked by limnoria and also a few teredo.  
 Balboa, C.Z. Much damage by limnoria and considerable marine growth. About 10 specimens of *Martesia* were recovered. The timber was thoroughly riddled by teredo, some  $\frac{1}{8}$  inch in diameter and one 15 inches long. Teredo were in both heart and sap wood, also in treated area. Test closed.  
 Supt. of Lighthouses, San Juan, P.R. Slight limnoria attack, no teredo.  
 Southern Pacific Company, Oakland Pier. Very light limnoria attack.  
 Southern Pacific Co. Peralta Pier. Very light limnoria attack.  
 Puget Sound Navy Yard. Pieces practically destroyed in first year.  
 Pearl Harbor, H.I. Navy Yard. Piece at Coaling Plant shows heavy limnoria attack and attack by *Martesia* and probably teredo while piece on the Marine Railway seems to be less heavily attacked.  
 Cavite, P.I. Naval Station. No report received.

**"G" TREATMENTS:**

Fort Tilden, N.Y. Limnoria attack in one piece,  $\frac{3}{4}$ -inch deep in places and  $\frac{1}{2}$ -inch on other piece.  
 Castle Pinckney, S.C. Lightly attacked by limnoria.  
 Naval Air Station, Pensacola, Fla. One piece  $\frac{5}{8}$  eaten away by limnoria and the other heavily attacked.  
 Balboa, C.Z. Limnoria damage severe. A section was cut from the end. It had a few pholads. Teredo were plentiful in both sap and heart wood and in treated section. Most of the teredo were dead.  
 Supt. of Lighthouses, San Juan, P.R. Heavily attacked by both limnoria and teredo. Test closed.  
 Southern Pacific Co. Oakland Pier. Very light limnoria attack.  
 Southern Pacific Co. Peralta Pier. Very light limnoria attack.  
 Puget Sound Navy Yard. Medium limnoria attack.  
 Pearl Harbor, H.I. Navy Yard. Medium limnoria attack.  
 Cavite, P.I. Naval Station. No report.

### COPPER RESINATE TESTS

A few of these test pieces remained at various test stations, but have now been practically all destroyed by limnoria, teredo and pholads. These test pieces were all submerged in 1930.

### SAN FRANCISCO BAY CREOSOTE TESTS

REPORT OF INSPECTION AUGUST 23, 1933 OF SPECIMENS FURNISHED DR. HERMANN VON SCHRENK AND COL. WM. G. ATWOOD, AND INSTALLED IN SAN FRANCISCO BAY AREA  
 (P = Pine F = Fir)

#### Barrett Manufacturing Company Material

Placed at Station B, Pier 7, San Francisco, January 1923. Moved to Biological Station Oakland Pier, % S.P. Co. December 1925. These specimens still show no attack except lightly by Limnoria.

| <i>Specimen</i> |            | <i>Condition August 23, 1933</i>                          |                                                                                                                    |

|                 | F-8        | Coke Minus Fraction 270 deg. C. 360 deg. C.               | No fresh attack.                                                                                                   |
| B-10            | F-9        | Vertical Retort Original Oil                              | Light limnoria attack on ends.                                                                                     |
|                 | F-10       | " " Minus solids                                          | " " " " "                                                                                                          |
|                 | F-11       | " " acids                                                 | " " " " "                                                                                                          |
|                 | F-12       | " " bases                                                 | " " " " "                                                                                                          |
| B-11            | F-13       | Vertical Retort Minus residue about 360 deg. C.           | Very light limnoria attack on one end.                                                                             |
|                 | F-14       | Vertical Retort Minus Fraction 230 deg.-270 deg. C.       | No fresh attack in 1933.                                                                                           |
|                 | F-15       | Vertical Retort Minus Fraction up to 230 deg. C.          | " " " " "                                                                                                          |
|                 | F-16       | Vertical Retort Minus Fraction 270 deg. C.-to 360 deg. C. | Light limnoria attack.                                                                                             |

## 1933 REPORT ON TEST PILES

The following Tables 1-A to 1-D, give the 1933 condition of four sets of Test Piles driven in 1919 and 1920 at Seattle, Tiburon, in San Francisco Bay, San Pedro and San Diego. Each set originally consisted of seven piles, including the following:

|                                                               |           |           |
|---------------------------------------------------------------|-----------|-----------|
| 3 Old creosoted fir piles originally driven .....             | 1890      | Table 1-A |
| 1 ditto .....                                                 | 1901      | " 1-B     |
| 2 New freshly creosoted fir piles originally driven 1919-1920 |           | " 1-C     |
| 1 New untreated fir pile originally driven.....               | 1919-1920 | " 1-D     |

The untreated piles were destroyed in three or four years as shown in Table 1-D, leaving six piles in each set.

The set at San Diego was exposed for test by the Atchison, Topeka & Santa Fe Railway Company in their wharf No. 63, until the wharf was dismantled in 1925. After being repaired they were redriven by the Southern Pacific Company at Long Beach, California and the test continued.

It has been customary to make an annual diver inspection of the test piles which the Northern Pacific installed under its Dock No. 1 at Seattle, but as inspections of recent years have shown these piles entirely free from Teredo, the diver inspection at Seattle was not made in 1932, and data of 1933 inspection had not been received at the time of forwarding the 1933 report.

TABLE 1-A

Creosoted fir piles from Southern Pacific Company Old Long Wharf, Dock "A" Oakland, originally driven in 1890. Pulled in 1919 and redriven elsewhere. Exposed to Marine Borer attack forty-three years to date.

| G :                                         | Dock A Pile 32 1890 - 1919 :     | " " " " "                                                                             |  |
| H :                                         | :                                | " " " " "                                                                             |  |
| I :                                         | :                                | " " " " "                                                                             |  |

The only sign of live teredos working was on Pile A and this was slight. This pile is as good as perfect in spite of the slight action noted.

Signed E. E. Hopkins

|                |                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------|
| Piles E, F, G. | From S. P. Ry. had been in service in Long Wharf, Oakland, Cal., Dock A, from 1890-1919, 22 years. Removed Apr. 12, 1919.   |
| Pile D.        | From same company, had been in service in same wharf, Dock E, 1901-1919, 18 years. Removed April 1919.                      |
| Piles A, C.    | From same company, freshly treated August 1919 but not previously used. Boiling process, 14 pounds creosote per cubic foot. |
| Pile B.        | From same company, not treated, but needed and driven in same condition as received.                                        |
| Pile H.        | Freshly treated, Pacific Creosoting Company March 1919, boiling under vacuum, 14 pounds creosote per cubic foot.            |
| Pile I.        | Freshly treated, Coleman Creosoting Company March 1919, steaming process, 16 pounds creosote per cubic foot.                |

Object of test to find out if possible how water in Puget Sound at Seattle compares with San Francisco Bay, Oakland, Cal., with reference to activity of marine borers also if preservative used in long lived Oakland piling had a more retarding effect on the borers than that generally used at Puget Sound points.

### CHEMICAL WARFARE SERVICE

Through the cooperation of the Chemical Warfare Service, we are able to present the following report on the work in their laboratory at Edgewood Arsenal and their tests at Beaufort, N. C.

#### Report on Tests at Beaufort, N. C., Marine Piling Investigation

(I.) FIRST SERIES. Test pieces  $30'' \times 10'' \times \frac{7}{8}''$ , referred to in A.R.E.A. Bulletin 332, December, 1930, pp. 297-303.

The terrapin pens holding these test pieces were washed out by a storm in March, 1932. Following the storm, one test piece from each set was salvaged and reinstalled in the open sea, where it had been found the attack was more severe.

To date, the following boards have survived without serious attack by either shipworm or limnoria:

| <i>Set No.</i> | <i>Vehicle</i> | <i>Toxic</i>                      |
|----------------|----------------|-----------------------------------|
| 4.....         | C              | DM                                |
| 9.....         | C + FO         | Cu Resinate                       |
| 13.....        | C              | —                                 |
| 25.....        | C              | —                                 |
| 40.....        | C + A + N      | CH <sub>3</sub> AsO               |
| 45.....        | C + N          | Bromacetophenone                  |
| 46.....        | C + N          | DNP                               |
| 47.....        | C + N          | C <sub>6</sub> H <sub>5</sub> AsO |

#### Abbreviations:

|     |                            |
|-----|----------------------------|
| A   | — Anthracene               |
| C   | — Creosote                 |
| DM  | — Diphenylaminechlorarsine |
| DNP | — Dinitrophenol            |
| FO  | — Fuel Oil                 |
| N   | — Naphthalene              |

All boards containing AsCl<sub>3</sub> showed practically no attack, but were so badly burned by the toxic as to be useless for structural purposes. Consequently, they were discarded.

(II.) SECOND SERIES. Test pieces  $8'' \times 4'' \times \frac{3}{4}''$ .

A. APPARATUS AND PROCESS.—The impregnations were made in an apparatus designed and assembled at Edgewood Arsenal. It consisted essentially of an impregnating chamber and a supply tank. It was equipped with suitable fittings and gages to make an impregnation by the vacuum-pressure process.

#### B. MATERIALS.

##### 1. Vehicles.

The following vehicles for carrying the toxics, both alone and in combination, have been used:

a. *Creosote*, A.W.P.A. No. 1. The distillation range and float test of the creosote used complied with the specifications for creosote, A.W.P.A. Grade 1.

b. *Creosote* minus the fraction distilling below 235°C. Sixteen liters of creosote were distilled and the fraction coming over below 235°C. was rejected. The remaining material was used in comparison with the original creosote.

c. *Chlorinated Creosote*. A number of impregnations were made with chlorinated creosote. The creosote was cooled to 15°C. and the chlorine bubbled through for various lengths of time. The chlorine absorbed was determined by the increase in weight of the creosote. This material was brushed on as well as impregnated into the wood by the vacuum-pressure process.

d. *Residuum Oil*. The residuum oil used was obtained from the Standard Oil Company. The analysis of the oil used was as follows:

|                         |                    |
|-------------------------|--------------------|
| Specific Gravity .....  | 0.9885 at 98.9°C.  |
| Viscosity Saybolt ..... | 58 sec. at 98.9°C. |

This oil has no toxic properties but acts as a water repellent. A sample of petroleum residuum was also obtained from the Santa Fe Railway Co. This oil is used by them mixed with creosote to impregnate railroad ties.

e. *Petroleum Oil*. The light oil used was obtained from the Standard Oil Company.

f. *Furfural*. This material was used due to its property of penetrating wood deeply and its solvent action on DM. Ammonia gas was used in some cases to lock the DM and furfural in the wood. The hydrofuranide formed by their interaction is less soluble than furfural.

## 2. Toxics.

The per cent of toxic used was based on the weight of the vehicle. There have been innumerable toxics impregnated into wood to increase its serviceable life. The toxics usually used are salts of copper and arsenic, phenols, cresols, lysol, etc. A great many patents have been taken out on the use of the various toxics. It is to be noted that practically all toxics tried are toxic to men, while their toxicity to borers is not definitely proved.

The following compounds have been tested in wood since 1929:

Furfural  
Triethanolamine oleate  
DM  
DM and Furfural  
DM and Furfural +  $\text{NH}_3$  gas.  
Chlorinated Creosote  
Colloidal Copper from Asphalt Product Co.  
Dichlorxylenol  
Ethylenedichloride  
Triphenylarsine  
Methylarsenious Oxide  
Benzylarsonic Acid  
Dinitrophenol  
Phenyldichlorarsine  
Phenylarsenious Oxide  
Hydrofuranide  
Paris Green  
Diphenyl  
Copper Sulfate  
Potassium Ferrocyanide

These toxics were tested in various percentages, alone and in combination, after impregnating in wood.

## 3. Wood Test Pieces.

The wood in which the toxics and vehicles were tested was a good grade of pine. Wood is readily attacked by borers and while some tropical species have shown some resistance, pine is quickly attacked and riddled by borers. The air seasoned pine was sawed into  $8 \times 4 \times \frac{3}{4}$ -in. sections which after impregnating are termed "test pieces". The pieces having defects such as knots, checks, etc., were used as the bait pieces to

accelerate attack on the impregnated test pieces. In a majority of cases, the test pieces had a toxic in solution in the impregnating vehicle. Where a toxic was not included it was for the purpose of getting a comparison on the vehicle with and without a toxic.

#### (C.) INSTALLATION OF TEST PIECES AT PIVER'S ISLAND, BEAUFORT, N. C.

The method of installation was as follows:

Each  $8 \times 4 \times \frac{3}{4}$ -in. test piece had a No. 9 screw-eye fitted in the center of one of the  $8 \times \frac{3}{4}$ -in. sides. When ready to install, a  $\frac{1}{4}$ -in. cable was threaded through the screw eyes. The test pieces were kept separated by a flexible wire wound on a 3d nail driven in the  $4 \times \frac{3}{4}$ -in. end. Two steel stakes were driven in the water and the ends of the cable and wire were attached to the stakes. The test pieces installed in this manner have withstood a number of severe storms. The installation of new impregnated pieces was usually made in March or April of each year.

The intensity and distribution of attack were determined by nailing blocks of unimpregnated wood to alternate test pieces. These blocks, which are termed "baits", are ordinarily destroyed by borers in one season, and must be replaced each year by new ones.

When the bait pieces become too crowded, the shipworms are forced to seek entry into the impregnated pieces, thus giving a measure of the efficiency of the toxic against the adult borer.

Since some of the vehicle and toxic in an impregnated test piece may be transferred to the attached bait piece by contact or by leaching, thus inhibiting attack on the baits by borers, controls of untreated wood were installed at regular intervals along with the treated pieces. It may be mentioned here that this effect of a protected area around an impregnated test piece has never been noted, still the possibility exists and must be allowed for. These control pieces usually have disappeared after one season, leaving nothing but the screw eye to show where they were originally placed on the line.

There have been 736 numbered test pieces installed and tested in this series. The numbering is progressive and increases a hundred each year. As listed in Table 1, the first set included 125 to 180. These pieces were first installed for test in a fish pond on April 3, 1930. (The fish pond is a space enclosed by cement walls and connected to tide-water by a gate). This set was staked outside the walls on April 5, 1932. The set numbered 245 to 293 was installed in the fish pond on April 13, 1931. On October 10, 1931 they were staked outside the sea wall. The test pieces numbered 300 to 355 were installed outside the sea wall in their present location on April 5, 1932, and the 400 series in April, 1933.

#### (D.) INSPECTION OF TEST PIECES.

The inspection of the test pieces for borer attack is made in October. This month is about the end of the breeding season for shipworm at Beaufort, N. C. The inspection is made by removing the cables on which the test pieces are strung, together with the attached test pieces, from the water. Each test piece is given a thorough inspection for limnoria and shipworm attack. All the barnacles and oyster spat are removed from the piece during this examination, as the accumulation of barnacles and oyster spat reduces the area available for attack. The nail used in the test piece is pulled and any corrosive effect of the toxic or vehicle noted. When the inspection is completed new bait pieces and controls are put on and the line replaced for further test. The method of installation and the effect of borers on test pieces are shown in photograph No. 6198.

#### (E.) EXPERIMENTAL RESULTS.

In the following table, the number, vehicle, toxic, pieces installed, pieces attacked, kind of attack (whether limnoria or shipworm), pieces discarded, rating, and pound per cubic foot, are noted.

The column "Rating" gives an approximation of the comparative efficiency of the particular set. Test pieces attacked by shipworm are discarded as of no value. The limnoria attack is rated on the area and depth of attack. The figure for rating is derived from the numerical values in the following list, which are measures of the degree of destruction of the wood:

|                             |      |
|-----------------------------|------|
| No attack .....             | 0    |
| Very slight limnoria .....  | 5%   |
| Slight limnoria .....       | 10%  |
| Moderate limnoria .....     | 15%  |
| Considerable limnoria ..... | 25%  |
| Heavy limnoria .....        | 50%  |
| Shipworm discarded .....    | 100% |

An example of the figures for a set; four boards in the set, two showing slight limnoria attack, one showing moderate limnoria attack, and one attacked by shipworm:

$$10 + 10 + 15 + 100 = 135$$

$$100 \frac{(135)}{(4)} = 66.3 \text{ rating.}$$

(F.) The following abbreviations are used in the tables:

|                               |                         |
|-------------------------------|-------------------------|
| BA — Benzyl arsonic acid      | LO — Light Oil          |
| BO — Brushed on               | PDA — Phenylchlorarsine |
| C — Creosote                  | PG — Paris Green        |
| DCX — Dichlorxylenol          | RO — Residuum Oil       |
| DM — Diphenylaminechlorarsine | SFO — Santa Fe Oil      |
| DNP — Dinitrophenol           | TPA — Triphenylarsine   |
| EO — Triethanolamineoleate    |                         |
| F — Furfural                  |                         |
| H — Hydrofuramide             |                         |

Method of Installation of Marine Piling Test Pieces

Object: To determine resistance of impregnated test pieces to attack by marine borers.

Description: Two strings of  $8 \times 4 \times \frac{3}{4}$  inch pine test pieces, after removal from water, showing

- Supporting cable,  $\frac{3}{8}$  inch, threaded through screw-eyes in test pieces.
- Wire,  $\frac{1}{8}$  inch, nailed to ends of test pieces to keep them separated.
- String of test pieces as removed.
- After inspection and ready for reinstallation, with new bait pieces and controls.

Project: F 92, Marine Piling.

Dates: Installed at Beaufort, N. C. by Research Division, April 13, 1931. Photographed at Beaufort, N. C., October 5, 1931.

Table 1

Inspection Results on Impregnated Test Pieces

| Set No. | Vehicle | Toxic | Discarded | Shipworm | No. Attacked | No. Installed | Inspection Rating               |
|---------|---------|-------|-----------|----------|--------------|---------------|---------------------------------|
|         |         |       |           |          |              |               | 1930 : 1931 : 1932 : Lbs./cuft. |

## DISCUSSION OF RESULTS

## (A) UNIMPREGNATED BAITS AND CONTROLS.

The increased attack incited by bait pieces is illustrated by comparing the attack on similar test pieces with and without baits. Two hundred twenty-four (224) test pieces were compared, 112 with and 112 without baits. Forty-four per cent of the test pieces without baits showed attack, while 76 per cent of the test pieces with an attached bait were attacked. The practically complete destruction of all bait pieces and controls in one season shows the heavy infestation of borers in these waters. In most cases the crowded condition of the bait forces attack on the test piece. This is evident, after removing the bait, by the large number of nicks in the test piece.

## (B) TEST PIECES.

Two sets, No. 151 and 155, subjected to attack for 3 seasons showed neither limnoria nor shipworm attack. The vehicle used in No. 151 was creosote + 10 per cent furfural, to which 2 per cent DM was added as the toxic, and in No. 155 was the same with a second treatment with ammonia. The addition of the furfural probably increased the solubility of the DM in creosote.

Since toxics vary considerably in water solubility, the possibility that this variation might be the determining property was investigated. In one set methylarsenious oxide, which is very soluble in water, was used; in another set, phenylarsenious oxide, which is very slightly soluble, was used. Both are soluble in residuum oil, which was used as a vehicle, at least to the extent to which they were added. None of these solutions was of any value in protecting wood.

A comparison of the average of the rating values of test pieces impregnated with creosote, light oil and residuum oil, with and without toxics, is made in Table 2. The relation between rating and lb./cu. ft. of creosote is shown in Table 3, and between creosote and creosote + toxics, in Table 4.

| Residuum Oil .....       | 12                 | 12     | 12 | 0.0                    | 17.8                      |
| Light Oil .....          | 4                  | 4      | 4  | 0.0                    | 18.0                      |
| Creosote + TPA .....     | 12                 | 10     | 2  | 75.8                   | 17.6                      |
| Residuum Oil + TPA ..... | 12                 | 12     | 12 | 0.0                    | 7.2                       |
| Creosote + DCX .....     | 12                 | 10     | 1  | 82.5                   | 20.7                      |
| Light Oil + DCX .....    | 8                  | 8      | 8  | 0.0                    | 12.2                      |

These comparisons show that residuum oil and light oil have very little value, compared to creosote, even when reinforced by toxics. Residuum oil is much more difficult to inject in wood than creosote and the less number of pounds per cubic foot impregnated reduces the amount of toxic taken up by the wood.

TABLE 4

Comparison of Test Pieces Impregnated with Creosote and with Creosote Plus Toxics

|                        | No. Test<br>Pieces | Attack |   | Average<br>Rating 1932 | Av. Number<br>lb./cu. ft. |
|------------------------|--------------------|--------|---|------------------------|---------------------------|
|                        |                    | L      | S |                        |                           |
| Creosote alone .....   | 34                 | 29     | 7 | 72.8                   | 21.9                      |
| Creosote + toxic ..... | 26                 | 22     | 4 | 77.3                   | 19.4                      |

This comparison indicates a slight advantage in adding toxic to creosote, but this is not believed to be significant on account of the short time of the test. These results have forced the conclusion that to get reliable results on toxics quickly, it is necessary to use some vehicle other than creosote. For these reasons the Chemical Warfare Service is increasing the use of residuum oil as the toxic carrier in this work.

### Conclusions

1. No definite conclusions can be drawn as to the value of creosote reinforced with toxics as compared with creosote alone, since the test pieces have been exposed for too short a time, in no case over three years.

2. Due to the long life of creosote alone, it is believed advisable to test the effectiveness of toxics in some vehicle having little or no protective value alone, such as a petroleum residuum oil.

### "SEA ACTION COMMITTEE"

#### INSTITUTION OF CIVIL ENGINEERS—ENGLAND

The 13th Interim Report published in June 1932 was received.

Attention has been called in previous abstracts to the tests of corrosion of metals being carried on by this committee and the fact that some rather generally accepted ideas, especially as to the resistance of the so-called "irons", were not confirmed by these tests. The report under discussion contains detailed reports on the specimens exposed above high tide, in the tidal range and below low tide at Halifax, N. S. and Auckland, N. Z. for ten years. The results of both the five and ten year laboratory inspections so far as indicated by loss in weight are shown in the following table.

#### LOSS IN WEIGHT PER 1000 SQ. C. M.

It will be seen that there is considerable difference in the relative value of the different metals and alloys depending on the exposure but there seems to be no question as to the superiority of the high nickel steel under all conditions of exposure except for the cast irons under some conditions. The three wrought irons tested were distinctly inferior to the mild steels under the same conditions and still more corroded than the copper steel; with the single exception of the 10 year test at Auckland.

Water and atmospheric conditions are responsible for the greater corrosion shown at Auckland than at Halifax.

The report also contains photographs of many specimens and information as to the kind of corrosion present in the various test pieces.

No new experiments were started with impregnated timber, but a progress report is made on the naphthalene tests initiated in 1930. These test blocks which were installed for test at Kilindini, Kenya Colony and Mauritius were treated by the Bethell process as follows:—

1. Crude naphthalene.
2.  $\frac{2}{3}$  crude naphthalene,  $\frac{1}{3}$  creosote.
3.  $\frac{1}{3}$  crude naphthalene,  $\frac{2}{3}$  creosote.
4. Creosote.
5. Creosote followed by naphthalene, with a view to prevent the leaching out of creosote.
6. Crude naphthalene plus 3 per cent. D.M. (chlorodihydrophenarsazine).

One hundred and twenty blocks (twenty impregnated with each mixture) were sent to Kilindini, and a similar set was sent to Mauritius. A few blocks have been returned after an exposure of 12-18 months. They indicate the unexpected conclusion, which is subject to confirmation by later examinations, that mixtures 2 and 3 are less effective than either 1 or 4. The reason for this is apparently to be sought in the less effective penetration of mixtures 2 and 3, of which on the average smaller quantities were absorbed than of substances 1 and 4. Crude naphthalene penetrates well and crystallizes out inside the wood, where it is readily recognized after the block has been split. While it undoubtedly confers some protection, naphthalene appears however to be less efficient than creosote. Since creosote alone has so far afforded full protection, no conclusions can be drawn regarding treatment 5; however, analysis after a prolonged exposure may show that tar acids are retained better when creosoting is followed by treatment with naphthalene. In the mixture 6 naphthalene is chiefly interesting as a vehicle for D.M., and this mixture has, during the short exposure so far investigated, protected the timber as completely as creosote.

Tests of block impregnated with fuel oil as a carrier are somewhat similar to those being carried on by this committee with the specimens prepared by the Chemical Warfare Service. They are reported as follows:

The eighth series of timber blocks were prepared to test fuel-oil as a vehicle for D.M. Four mixtures were used, namely: creosote alone, creosote plus 3 per cent of D.M., fuel-oil alone, and fuel-oil plus the same percentage of D.M. Thirty blocks of

each kind, making a set of 120, were exposed at each of three stations—Bermuda, Jamaica and Takoradi—in June and November, 1929, and January, 1930 respectively. While many blocks have disappeared, particularly at Takoradi, those which have been returned from Bermuda and Jamaica definitely show that the fuel-oil by itself has had no protective action, and that fuel-oil plus 3 per cent. of D.M. has protected, so far completely, the parts of the timber to which it has penetrated.

Creosote, both alone and with D.M. affords complete protection for several years, and therefore these tests will not allow any beneficial effect of adding D.M. to creosote to be observed for a long time. The particular fuel-oil used penetrated the blocks very badly, usually only a small part of the block being impregnated. If the fuel-oil contains D.M. that part alone is fully protected: there is a sharp line of demarcation, in contrast to the gradual transition observed with creosote. The non-impregnated portion is generally riddled with *Teredo* channels, right up to the line of demarcation, where they abruptly stop, showing the deterrent effect of D.M. even on the vigorous adult borer.

The main problem is to make the fuel-oil penetrate throughout the block. This difficulty is already apparent from the increases in weight on impregnation of various test-blocks recorded by Professor Dixon. Generally this increase with fuel-oil was about one-fifth of that with creosote, and a good deal of the fuel-oil was moreover quite near the surface. Crude naphthalene, a hydro-carbon, and Pintsch gas tar, apparently consisting also largely of hydro-carbons, penetrate completely, as does creosote, and it does not seem impossible that a variety of fuel-oil may be found which does penetrate satisfactorily. A suitable vehicle for D.M. would be very useful. It must be cheap, particularly since the price of creosote, which is quite efficient by itself, has fallen considerably since the Committee's investigations began; crude naphthalene costs about as much as creosote; and the only solution would appear to be in a natural oil, and possibly in some method of drying wood more completely.

In general the failure of large creosoted timbers is probably to be attributed to inadequate impregnation, or damage to the impregnated surface layer, rather than to inefficiency of the creosote.

The report also contains information regarding the deterioration of reinforced concrete in sea water and tests of the resistance of various native timbers and greenheart to marine borer attack at Rangoon, Burma.

These timber tests were started in 1922 and are reported in "Burma Forest Bulletin No. 28, Rangoon, 1932" but the period of exposure of the specimens reported was only from one to two years. All untreated timbers were attacked but no creosoted specimens including greenheart showed much attack.

## SUMMARY

The Panama tests show that several of the tropical timbers under test have high resistance, especially those containing silica.

Series No. 1 Chemical Warfare Service have now been under test for 8 years.

The copper carbonate treatment showed considerable resistance but all pieces have been attacked and some of them destroyed.

The fuel oil D.M. and phenyldichlorarsene treatment also showed resistance but again these pieces are practically all gone and were quickly attacked by limnoria.

The creosote D.M. pieces are still under test and none of them with the exception of one at Charleston, S. C. has been seriously damaged.

The test on Series No. 2 of the Chemical Warfare Service has been far too short a time to give final results but the three petroleum treatments all show greater or less attack.

The attack on the San Francisco Bay specimens is still too light after 10 years to give any indication as to the relative value of the different creosotes.

The report of the "Sea Action Committee" of the Institution of Civil Engineers does not show results very much different from those of this committee and no very definite conclusions can be drawn.

## Conclusion

Your Committee recommends that this report be accepted as information.

## Appendix D

### (4) SPECIFICATIONS FOR TREATMENT OF AIR-SEASONED DOUGLAS FIR

R. S. Belcher, Chairman; F. D. Mattos, Vice-Chairman, Sub-Committee; H. R. Duncan, W. R. Goodwin, G. R. Hopkins, R. S. Hubley, H. E. Horrocks, A. J. Loom, G. P. MacLaren, Clyde Osborne, L. J. Reiser, Dr. Hermann von Schrenk, C. M. Taylor.

Last year, as a part of its report, your Committee presented as information Specifications covering the Treatment of Air-Seasoned Douglas Fir, which appear on Pages 478 to 482 of Vol. 34, recommending they be referred to other interested committees for consideration and criticism with a view to later presenting the specifications for inclusion in the Manual. Committee III—Ties, and Committee VII—Wooden Bridges and Trestles, were asked to collaborate, particularly as to the practice of incising ties and bridge timbers as covered by the Specifications.

These committees have approved the specifications as they appear in the Proceedings, and your Committee now present the specifications for inclusion in the Manual.

#### SPECIFICATIONS FOR THE TREATMENT OF AIR SEASONED DOUGLAS FIR

##### Material

Material for treatment shall be in accordance with the specifications of this Association. Special attention, however, is directed to the peeling and sapwood requirements of round timbers which have direct bearing on the quality of treatment which may be secured.

##### Peeling and Sapwood Requirements of Round Timbers

All round timbers shall be thoroughly peeled before treatment. No piece shall be considered thoroughly peeled unless all the rough bark and at least 80 per cent of the inner bark shall have been removed. In no case shall any piece of inner bark be over  $\frac{3}{4}$  in. wide or over 8 in. long, and there shall be 1 in. of clean wood surface between any two such strips. Should the strips of inner bark remaining on the pole be less than  $\frac{3}{4}$  in. wide, the clear space required between any two such strips may be proportionally less than 1 in. No circumference may have more than 20 per cent of its surface covered with inner bark, although the entire surface of the pole may contain less than the allowable 20 per cent.

Piling and poles shall have sapwood of a minimum thickness of 1 in. at the butt end.

##### Seasoning

Douglas fir shall be air seasoned under conditions in accordance with the recommended practice of this Association. Since the rate of seasoning varies with the latitude, time of year, the exposure, and the climatic peculiarities of the season, it is essential to establish the seasoning period for each class of Douglas fir for any particular locality. The seasoning period shall be of sufficient length to reduce the moisture content of the marginal two inches of any cross-section of round or sawed timbers to 20 per cent, or less, of its oven dry weight. In material less than 4 in. in thickness, entire cross-sections shall be considered.

### Adzing, Boring and Framing

Insofar as practicable, all adzing, boring and framing of all kinds shall be done before treatment to minimize subsequent cutting through the treated shell and exposure of untreated wood.

### Incising

All sawed Douglas fir shall be incised two sides and two edges, using incisor teeth not more than  $\frac{5}{32}$  in. thick. Incisions  $\frac{3}{4}$  in. in depth are recommended for all sawed fir six inches thick or over, and  $\frac{1}{2}$  in. in depth in sides and  $\frac{3}{4}$  in. in the edges of all sawed fir less than 6 in. and more than 2 in. in thickness. Incising of material less than 2 in. in thickness is not recommended. The pattern recommended for the placing of the incisions is shown by Fig. 1.

### Grouping for Treatment

It is essential that Douglas fir be grouped properly in order that successful treatment may be obtained. Any charge shall be confined to pieces of approximately equal sapwood and moisture content, into which approximately equal quantities of preservative can be injected, and so separated as to insure contact of preservative with all surfaces.

## TREATMENT

### General

The ranges of pressure, temperature, and time duration shall be controlled so as to result in maximum penetration by the quantity of preservative injected, which shall permeate all the sapwood, and as much of the heartwood as practicable. The vacuum requirements stipulated are those of sea level and necessary corrections shall be made for altitude.

### Retention of Preservative

No charge shall contain less than 90 per cent nor more than 120 per cent of the quantity of preservative that may be specified; but the average retention of the preservative by the material treated under any contract or order shall be at least 100 per cent of the quantity specified.

The amount of preservative retained shall be calculated on the basis of preservative at 100° Fahr., from readings of working tank gages, or scales, or from weights before and after treatment of loaded trams on suitable track scales, with a correction for difference in moisture content, and checked as may be desired by the purchaser's representative.

### Determination of Penetration

Penetration shall be determined by sampling material in each charge, as may be desired by the purchaser's representative. Any holes which may be bored shall be filled with tight-fitting treated plugs.

### Plant Equipment

Treating plants shall be equipped with the thermometers and gages necessary to indicate accurately and record the conditions at all stages of treatment, and all equipment shall be maintained in condition satisfactory to the purchaser. The apparatus and chemicals necessary for making analyses and tests required by the purchaser shall also be provided by plant operators and kept in condition for use at all times.

### Preservative

The preservative used shall conform to one of the following standards of this Association.

Creosote, classes one, two or three.

Creosote-Coal Tar Solution.

Zinc Chloride.

### Amount of Preservatives to be Used—Douglas Fir for General Construction

#### (a) Creosote

Full Cell Process, not less than 10 lb. per cu. ft. of timber or to refusal.

Rueping Process, not less than 6 lb. per cu. ft. of timber.

Lowry Process, not less than 6 lb. per cu. ft. of timber.

#### (b) Zinc Chloride

Not less than  $\frac{1}{2}$  lb. of dry salt per cu. ft. of timber.

#### (c) Creosote-Zinc Chloride

Not less than 2 lb. of creosote and  $\frac{1}{2}$  lb. dry zinc chloride per cu. ft. of timber.

### Amount of Preservative to be Used—Douglas Fir for Use in Salt Water

Creosote—Not less than 12 lb. per cu. ft. of timber.

Other preservatives are not recommended for this class of service.

### TREATING OPERATIONS

#### Ties, Structural Timbers and Lumber of All Sizes

##### Creosote Treatments

### Heating

Preliminary to the pressure period, it may be found advantageous to heat the air-seasoned timber. When this is the case, the treating cylinder may be filled with the preservative heated to a temperature of 180° F. to 200° F. and held to as nearly 200° F. as possible for not more than 6 hr.

### Full Cell Process

Following the heating period, or as the first stage of the treatment, if no heating period used, a vacuum of not less than 22 in. shall be speedily created and maintained for a period of not less than 30 min. so that the timber may be as free from air as practicable. Without breaking the vacuum, the treating cylinder shall be filled with preservative heated to a temperature of 180° F. to 200° F. The pressure shall then be gradually raised to a maximum of 100 lb. per square inch over a period of not less than 30 min. nor more than 1 hr. and 30 min., and maintained until the quantity of preservative required to insure the final retention stipulated is injected into the wood, or failing this, until the purchaser's representative is satisfied that the largest volumetric injection that is practicable has been obtained. In no case, however, shall the period of maximum pressure exceed 12 hr. The temperature of the preservative during the pressure period shall not be less than 180° F. nor more than 200° F. and shall average at least 190° F.

After pressure is completed, the cylinder shall be emptied speedily of preservative and a vacuum of at least 22 in. promptly created and maintained until the timber can be removed from the cylinder free of dripping preservative.

### Rueping Process

Following the heating period, or as the first stage of the treatment, if no heating period is used, the timber shall be subjected to air pressure of sufficient intensity and

duration to provide, under a vacuum, the ejection of surplus preservative and to insure proper distribution and maximum penetration of the stipulated number of pounds of preservative per cubic foot of wood.

The preservative shall be introduced between 180° F. and 200° F., the pressure being maintained constant until the cylinder is filled with preservative. The pressure shall then be gradually raised over a period of not less than 30 min. nor more than 1 hr. and 30 min. to a minimum of 125 lb. per square inch and maintained within a maximum of 175 lb. per square inch, but in no case shall exceed 100 lb. more than the air pressure used, until there is obtained the largest practicable volumetric injection that can be reduced to the required retention by a quick high vacuum, or, failing this, until the purchaser's representative is satisfied that the largest volumetric injection that is practicable has been obtained. In no case, however, shall the period of maximum pressure exceed 12 hr. The temperature of the preservative during the pressure period shall be not less than 180° F., nor more than 200° F., and shall average at least 190° F.

After pressure is completed, the cylinder shall be emptied speedily of preservative and a vacuum of at least 22 in. promptly created and maintained until the timber can be removed from the cylinder free of dripping preservative. As an alternative, both additional heat and vacuum may be applied as follows. After pressure is completed and before removal of preservative from the cylinder, the preservative surrounding the timber may be heated to a maximum of 220° F., the steam to be turned off the heating coils immediately the maximum temperature is reached. The preservative shall then be removed from the cylinder and a vacuum applied as specified above.

### Lowry Process

Following the heating period, or as the first stage of the treatment, if no heating period is used, the treating cylinder shall be filled with the preservative, heated to a temperature of 180° F. to 200° F. Pressure shall then be gradually raised to a maximum of 100 lb. per square inch over a period of not less than 30 min. nor more than 1 hr. and 30 min. and maintained until there is obtained the largest volumetric injection practicable that can be reduced to the required retention by quick high vacuum, or, failing this, until the purchaser's representative is satisfied that the largest volumetric injection that is practicable has been obtained. In no case, however, shall the period of maximum pressure exceed 12 hr. The temperature of the preservative during the pressure period shall not be less than 180° F. nor more than 200° F. and shall average at least 190° F.

After pressure is completed, the cylinder shall be emptied speedily of preservative and a vacuum of at least 22 in. promptly created and maintained for not less than 30 min. until the quantity of preservative injected is reduced to the required retention and the timber can be removed from the cylinder free of dripping preservative. As an alternative, both additional heat and vacuum may be applied as follows. After pressure is completed, and before removal of preservative from the cylinder, the preservative surrounding the timber may be heated to a maximum of 220° F., the steam to be turned off the heating coils immediately the maximum temperature is reached. The preservative shall then be removed from the cylinder and a vacuum applied as specified above.

### ZINC CHLORIDE TREATMENT

The treating solution shall be no stronger than necessary to obtain the required retention of preservative with the largest volumetric absorption practicable and shall be thoroughly mixed before use.

The timber shall first be subjected to a vacuum of not less than 22 in. for at least 30 min. before the preservative is admitted to the cylinder. The preservative shall be

introduced between 180° F. and 200° F., without breaking the vacuum until the cylinder is filled. The pressure shall then be gradually raised to a maximum of 100 lb. per square inch over a period of not less than 30 min. nor more than 1 hr. and 30 min. and maintained until the quantity of preservative required to insure the final retention stipulated is injected into the wood, or until less than 2 per cent of the total quantity required has been injected during the latter half of one hour throughout which the rate of injection has persistently decreased while the pressure has been held continuously at the maximum. In no case, however, shall the period of maximum pressure exceed 12 hr. The temperature of the preservative during the pressure period shall not be less than 180° F. nor more than 200° F. and shall average at least 190° F.

After the pressure is completed, the cylinder shall be speedily emptied of preservative and a vacuum promptly created and maintained until the timber can be removed from the cylinder free of dripping preservative.

#### CREOSOTE-ZINC CHLORIDE TREATMENT

The preservative mixture shall be composed of the volumetric proportions of creosote and zinc chloride solution of the necessary strength required to obtain the stipulated retention with the largest volumetric injection that is practicable, and shall be agitated in the working tank and treating cylinder so as to insure thorough mixing before and while the cylinder is being filled with preservative and while the preservative is being injected into the timber.

The timber shall first be subjected to a vacuum of not less than 22 in. for at least 30 min. before the preservative is admitted to the cylinder.

The treating cylinder shall be filled with the mixture of preservatives heated to a temperature of 180° F. to 200° F. without breaking the vacuum. The pressure shall then be raised to a maximum of 100 lb. per square inch over a period of not less than 30 min. nor more than 1 hr. and 30 min. and maintained until the quantity of preservative required to insure the final retention stipulated is injected into the wood, or until less than 2 per cent of the total quantity required has been injected during the latter half of one hour throughout which the rate of injection has persistently decreased, while the pressure has been held continuously at the maximum. In no case, however, shall the period of maximum pressure exceed 12 hr. The temperature of the preservative during the pressure period shall not be less than 180° F. nor more than 200° F. and shall average at least 190° F.

After pressure is completed, the cylinder shall be emptied speedily of preservative and a vacuum promptly created and maintained until the timber can be removed from the cylinder free of dripping preservative.

#### TREATING OPERATIONS

##### Piles and Poles

Specifications for treating operations covering piles and poles are the same as those covering ties, structural timber and lumber, except that the period of maximum pressure of preservative in all treatments may be held to a limit of 16 hr. instead of 12 hr. as in the treatments of sawed timber.

#### Conclusion

Your Committee recommends the adoption of the above specification for publication in the Manual.

## Appendix E

## (5) DESTRUCTION BY TERMITES AND POSSIBLE WAYS OF PREVENTION

Dr. Hermann von Schrenk, Chairman, Sub-Committee; Wm. G. Atwood, C. C. Cook, L. H. Harper, G. R. Hopkins, F. D. Mattos, L. B. Shipley, W. A. Summerhays, C. M. Taylor.

The Committee on Termites has kept track of developments with reference to termites during the last year. These insects have been reported as extremely active from many points in the United States. The newspapers have given this subject wide publication, particularly at such points as Elkhart, Ind., where the termites attacked a school building, and also in the district about New York City and on Long Island. With a wider understanding of the type of destruction which they bring about, more and more people have watched for them.

In a brief report of this character, it is impossible to give all the points where serious attacks have been reported. It is of interest so far as the railways are concerned to note that the Committee has received one report of an attack on untreated piling in bridges in Louisiana, and, from the same state a report together with actual samples of their activity in a tie-seasoning yard. The insects built their tunnels across creosoted stringers and were beginning to attack the lowest tier of untreated oak ties when they were fortunately discovered. It goes to show that, particularly in the Southern country, all untreated wood should be very carefully watched and whenever the earthen tunnels appear, prompt positive measures should be taken.

One of the outstanding investigations of the year was undertaken during the past summer by the R.C.A. Communications, Inc., of New York. This test was undertaken in cooperation with the United States Bureau of Entomology for the purpose of testing the effect of various soil poisons. This test is considered by the Committee of such importance that a detailed statement regarding same follows herewith. The Committee expresses its appreciation to R. T. Rossi, Chief Engineer of the R.C.A. Communications, Inc., and to Dr. Thomas E. Snyder of the Bureau of Entomology for the following statement:

## EXPERIMENTS WITH CHEMICALS FOR PROLONGING THE LIFE OF POLES BY POISONING THE SURROUNDING SOIL

In cooperation with the R.C.A. Communications, Inc., of New York, the Bureau of Entomology of the U.S. Department of Agriculture began a series of soil poisoning experiments during the latter part of August and first part of September 1933, at Riverhead, L.I. Here the western red cedar poles were being damaged by subterranean termites. These poles mostly had been set in 1928 and had been given a brush treatment with "Carbosota" before placement. The soil which is Lakewood sand, is generally infested with termites.

In 1932 varying amounts of the sapwood of these poles had shaved or chipped away below the ground line. These areas of the poles had then been sprayed with "Carbosota".

In August and September, 1933, the earth was removed about each pole to the depth of 30 in. and then the poison was poured or layered in the soil near the pole to the ground line. One gallon of liquid was poured in trenches every 6 in. and the soil returned about the pile; where powder or crystals were used it was placed in trenches every 10 in. Using 10 men per 10 hour-day, 3 miles of pole line or 100 poles were treated per day.

Thirty different applications were placed under test on 281 poles using 28 different chemicals. Untreated infested check poles are included in this experiment. As a rule, 10 poles were treated with each poison; the poles are marked and their location plotted on a map.

The following chemicals are under test:

| <i>Compound</i>                                                             | <i>Amount Used<br/>Per Pole</i> |
|-----------------------------------------------------------------------------|---------------------------------|
| Sodium arsenite—10 per cent solution .....                                  | 5 gallons                       |
| " " —dry .....                                                              | 5 pounds                        |
| Copper arsenite .....                                                       | 5 pounds                        |
| Arsenic trioxide .....                                                      | 5 pounds                        |
| Lead arsenate .....                                                         | 4 pounds                        |
| Anaconda paste .....                                                        | 10 pounds                       |
| Zinc Meta Arsenite .....                                                    | 5 pounds                        |
| "Antimite" .....                                                            | 5 pounds                        |
| Sodium fluosilicate .....                                                   | 5 pounds                        |
| Copper sulphate .....                                                       | 5 pounds                        |
| "Hallowax" No. 1011 .....                                                   | 5 pints                         |
| Carbon bisulphide—35 per cent miscible (6 quarts to 50 gallons of water)... | 5 gallons                       |
| Orthodichlorobenzene .....                                                  | 5 gallons                       |
| Paradichlorobenzene .....                                                   | 5 pounds                        |
| Pyridine commercial No. 2 .....                                             | 5 gallons                       |
| Crude naphthalene .....                                                     | 5 pounds                        |
| Crank case oil .....                                                        | 5 gallons                       |
| " " " .....                                                                 | 10 gallons                      |
| Coal tar creosote—Grade 1 .....                                             | 5 gallons                       |
| Coal tar creosote 50 per cent, and "Panoline" (petroleum) 50 per cent....   | 5 gallons                       |
| Coal tar creosote 1 part, kerosene oil 3 parts .....                        | 5 gallons                       |
| "Reilly Transparent Penetrating Creosote" .....                             | 5 gallons                       |
| "Aczol" (10 per cent solution by volume) .....                              | 2 gallons                       |
| "Terminix" .....                                                            | 5 gallons                       |
| "Creol" .....                                                               | 5 gallons                       |
| "Cabinol" .....                                                             | 5 gallons                       |
| Salt .....                                                                  | 10 pounds                       |
| Chlorinated lime (30 per cent chlorination) .....                           | 5 pounds                        |
| Flake naphthalene .....                                                     | 2½ pounds                       |
| Zinc chloride .....                                                         | 5 pounds                        |

The test which the Committee reported last year which was installed in Florissant, Mo., in 1932, is still in progress. Possibly because of the extremely dry and hot summer, there was little or no termite attack indicated on the test pieces, so it was thought advisable to let the stakes remain for another year, at which time it is hoped that the Committee will be able to make a progress report.

Another series of tests of outstanding value are those undertaken by the Bureau of Entomology, under the direction of Dr. Thomas E. Snyder at Barro Colorado Island, Panama. The fourth progress report on this test was printed in detail in the 1933 Proceedings of the American Wood Preservers' Association. By permission of that association, your Committee gives the introduction to this report herewith as well as a number of the photographs showing the destruction of some of the principal specimens.

Introductory Paragraphs from:

#### AN INTERNATIONAL TERMITE EXPOSURE TEST—FOURTH PROGRESS REPORT<sup>1</sup>

By Geo. M. Hunt and T. E. Snyder

"The fourth report gives the latest inspection data on specimens of wood treated with various chemicals and exposed to the activities of termites in Australia, Barro Colorado Island (Canal Zone), Hawaii, and South Africa. Details of treatment, installation, and current inspections are given in the Proceedings of this Association for the past three years.

<sup>1</sup> From Proc. Am. Wood Preservers' Assn., 1933, p. 398.

"The test specimens were of sap pine about 2 by 4 by 18 inches in size. Four sets of such specimens were treated at the Forest Products Laboratory in 1928, one set for each of the four countries just named. Through the cooperation of Government officers in each country the specimens were installed in soil known to contain termites and inspections are made and reported at regular intervals. In 1931 a set of over 500 similar specimens was treated with a different series of chemicals and installed on Barro Colorado Island. Cost limitations made it impractical to send duplicates of this set to the other stations.

"Tables<sup>2</sup> show details as to the chemicals used, the absorptions, and the number of specimens at each exposure station and give the results of the inspections made at each station by the cooperating Government officers.

"These tables must not be considered as showing conclusively the relative effectiveness of the different preservatives. Comparison of the results from the different stations shows marked differences. For example, the nickel arsenate specimens are still sound at Barro Colorado Island, but in Australia all but one are either attacked or destroyed. On the other hand, the coal tar creosote specimens are sound in Australia and South Africa but are being attacked at Honolulu and Barro Colorado Island. These differences undoubtedly result from differences in climatic and exposure conditions and species of termites at the different stations, differences in amount or distribution of preservative in individual specimens, differences in the inspection methods and classification used by the several inspectors and perhaps other factors not yet recognized. The experiments should continue several years yet before conclusions are drawn. Use of these data for commercial promotion of any preservative is not warranted. . . . As the experiment grows older and a larger percentage of the more effective preservatives has failed it may be possible to show a definite relationship between the absorption and the life of the specimens in each preservative group. The depth and uniformity of penetration will, of course, have a very important influence for even with the best preservatives and good absorptions both termites and decay will sooner or later locate and destroy the places that have not been penetrated satisfactorily. Many of the specimens removed from test are being returned to Madison so that observations on penetration can be made when desired.

"The accompanying illustration shows the condition of some of the specimens removed from test at Barro Colorado Island at the time of the October 1932 inspection."

In addition to the stakes installed at Barro Colorado Island, the Bureau has a number of wooden framed wall-board buildings constructed of various woods both treated and untreated with the furnishing of treated furniture in a number of these buildings. No results have as yet been obtained from these test structures.

The Committee wishes again to emphasize that one of the most effective methods outside of the use of creosoted wood is to protect foundations, posts, pipes, etc., with metal shields. Fig. 1 shows a good type of shield around a concrete post. It would be better however to place this shield a foot or more higher than is indicated in the photo-

FIG. 1. Metal shield on concrete base, as a rule should be placed higher. (Photo sent by Dr. T. E. Snyder.)

<sup>2</sup> For these Tables consult the original article—See Note 1.

Typical specimens removed from test at Barro Colorado Island after  $4\frac{1}{4}$  years exposure. The preservatives used in the several specimens and their absorptions, in pounds per cubic foot, were as follows: (1) and (2) coal tar creosote 5.6 and 2.1, (3) halowax, 20.6, (4) and (5) zinc-meta-arsenite 0.58, (6) thallium sulphate 0.33, (7) sodium bicromate 0.68, (8) and (9) sodium fluosilicate 0.52 and 0.68, (10) Tanalith, 0.35, (11) arsenious acid, 0.71. Photo by James Zetek.

graph. Fig. 2 shows a number of buildings constructed by the Panama Administration. Particular attention is called to the spaces left between the top of the post and the concrete cap in which metal types of shields are to be inserted. This type of protection has now been made standard by the Government under Governor Burgess in the Canal Zone for all Government construction in that territory.

FIG. 2. Grooves  $\frac{1}{2}$ -inch wide above concrete posts going all around; into these grooves when the building is finished the metal termite shield is fitted. Note that the walls do not reach the concrete sills but that they stop 6 inches below the grooves in the posts making it unnecessary to use the linear type of shield. Note also on one of the posts reinforcement rods stick out for the concrete steps, which will be below the grooves for the shields. (Photo sent by Dr. T. E. Snyder.)

Members of the Committee witnessed the actual treatment of a large number of untreated chestnut poles of the Long Island Lighting Co. in central Long Island by the Pfister Process. This is a process (patented) developed by Rudolph Pfister, a Swiss engineer, who has constructed and developed a portable device for puncturing poles below, at and above the ground line. Various types of preservatives are injected into the poles. It is impossible to give details reference this process at this time, because no actual results are yet available. The process will be watched with much interest in the hopes of reporting the details of chemical efficiency of the distribution of the preservative, processes, etc. in the report next year.

The California Termite Investigations Committee which has been at work for a number of years, has announced the forthcoming publication of a large volume (900 pages with 181 figures and illustrations) entitled "Termites and Termite Control". This volume is made up of 56 chapters divided into four parts:

- Part I.—Termites and their Biology
- Part II.—Chemical Investigations
- Part III.—Termite Resistivity of Wood and Building Materials
- Part IV.—Prevention and Repair of Termite Damage

This volume should be of very great interest to all engineers and judging from the table of contents, it will be a standard reference book on this important subject. This volume will be available January 1, 1934, for \$5.00, which should be sent to the Sales Department, University of California, Berkeley, California. The Committee hopes at the time of the next annual convention to have a copy of this volume on hand for the personal inspection of those interested.

### NOTES ON THE WHARF BORER

In its last year's report, the Committee reported the appearance in the United States of the wharf borer (*Nacerda Melanura*, Linn). This insect has continued its activity in and around New York Harbor. The Committee is indebted to Ralph H. Mann for some further notes on this insect. During the last year, Mr. Mann visited the plant of the General Aniline Corporation at Linden (Grasselli), N. J. He and the Committee are indebted to Wm. Miller, General Manager of the Corporation and to O. P. Aimone, the Plant Engineer, for the following data. The plant is located on 65 acres of land, 23 acres of which are covered with buildings of brick with timber frames and with some concrete floors on wood sub-floors. All structures are on untreated timber piling. Mr. Aimone estimated the number of piles at about 7500. After a discussion with the officers of this Company, Mr. Mann reports as follows:

"The plant is situated about  $\frac{1}{2}$  mile west of the Arthur kill, a New York harbor tidal estuary. The structures are built on the New Jersey tidal marshes on hydraulic sand filled ground. High tide levels plus 6.5 ft. mean sea level. Ground elevation about plus 9.0 ft. I estimate the pile cut-off elevations at elevations of from plus  $1\frac{1}{2}$  to 2.0 ft. above the ground line or elevation 10.5 to 11.0 above mean sea level. Their trouble (and it is a big one) is with wood borers in the constantly wet wood. The wetness being due to salt water. Mr. Miller said that he had sent specimens of the borer larvae to Dr. T. E. Snyder (Entomologist, Bur. of Entomology) U. S. Department of Agriculture, Washington, D. C. and to Thos. J. Headley, entomologist of Rutgers college. These authorities advised Mr. Miller that the specimens were "*Nacerda Melanura* Linn". From the description by Mr. Miller and the name I identified this as the "wharf borer", the source of the trouble suffered recently by the New York Dock Co. in the pile heads under their wharves on the Brooklyn side of the East River in New York Harbor. Later, when inspecting the piles with Mr. Aimone, I readily identified the worm as the larvae of the "wharf borer". The damage is tremendous here, that done to the New York Dock Co.'s wharves cannot compare with it. The piles are riddled, many of them ruined and alive with the worms. Dr. Snyder's letter says that coal-tar creosote is the proper antidote. This company is heavily coating the piles least infected with creosote and are buying their first order of pressure creosoted timbers for replacements. One point of great interest as to the supposed hardness of these wharf borers was noted by Mr. Aimone. In the timbers and piles under the house where tanks of  $\text{Na}(\text{OH})_2$ —(sodium hydroxide) or caustic soda are stored, even though there is an ever present drip of this highly active chemical on the floor-beams and down to and over the piles, Mr. Aimone said that it was here that the borer attack was most severe. As to the drip danger, I was warned when in the building not to look up and so expose my eyes to possible drip of the caustic soda.

"I spoke to Mr. Miller this morning over the long distance telephone. I asked him the questions propounded by you in your letter:

"(a) The wharf borers were, Mr. Miller stated, the prime factors leading to the repairs now being made to the underpinning, (piles and low lying timbers) in the buildings of the General Aniline Corp. at Linden, N. J. At first before their definite knowledge of the wharf borer, the cause of the disintegration of the wood was always attributed to the oft-quoted "dry rot".

"(b) The infestation according to Mr. Miller today and also from my own observations made May 22, 1933, were in that portion of the pile within from the top two or three feet of the pile, or in that part of the pile that was continually dampened, not immersed, with which the salt water within the underlying soil was saturated."

"(c) The borers were discovered by chance. When the above noted caustic soda house developed leaking pipes, the flooring was torn up at the time that the repairs were

being made and the supporting piles disclosed. When these piles were cut into by the workmen and larvae were discovered in large numbers. This finding led Mr. Miller and Mr. Aimone to think that if such was the case under this building it might be the same for other foundations. The subsequent inspection of the piles under the other buildings proved the assumption to be correct. Mr. Miller said today that it was his opinion that when the piles were unearthed that spots of excessive 'decay' were disclosed. These spots when cut into with an axe or adze he said, would almost always bring to view many of the larvae. Mr. Miller advanced the opinion that he was probably fortunate in his discovery of the pests, because of the time in which his inspections were made. He said that the first knowledge he had of the borers, or their larvae was when they were in the 'worm' stage. He seems to feel that the borers may best be detected when they are in that stage of their life cycle. He first made the discovery of the larvae in March."

"(d) As to whether the borer attacks sound wood or wood in which decay has commenced, Mr. Miller is in doubt but he has heard of Dr. Snyder's statements concerning the Doctor's own doubts or lack of definite knowledge of this same point. Mr. Miller stated that he had a crew of men who were carefully painting creosote liberally on the heads of the uncovered piles that have been attacked as well as of those (few in number) which are as yet sound. This is in line with Dr. Snyder's recommendations. He says also that the darkness of the under floor seems to aid the propagation of the insects in the timber. However when I saw the plant last May, the piles that I was shown and from which I dug out many specimens of thriving borers was in piling in the outer tier of piles and on the southwest side of a building which I remember distinctly was very sunny.

"Mr. Miller thinks re' your advices to railroad port engineers, that the advice should be as to *when* to look as well as where. The *how* according to Mr. Miller is to look from 2 ft. above the line of permanent saturation upwards for 3 or 4 ft. Then if surface evidences of 'dry rot' are seen, the pile should be cut into with an axe, adze or hatchet and the wharf borers will be evident."

A second series of notes sent by Mr. Mann deals with the continued attack of these insects in some piles of the New York Dock Company, 334 Furman St., Brooklyn, New York. Through the courtesy of Mr. Driver, Chief Engineer of the New York Dock Company, we are able to give the following notes:

"This afternoon, I made an appointment with L. E. Driver Chief Engineer, New York Dock Company, 334 Furman Str., Brooklyn, N. Y. The results of this call, in answer to your stated inquiries are:

"(a) Here the prime factors leading to the repairs to the 250 odd pile heads recently renewed by the New York Dock Company were the presence of heavy decay in the upper 3 ft. of the pile head. In most instances, Mr. Driver said, the decay was the result of the infestation of the wharf borers. For, when the infested and decayed pile heads were cut into, the larvae of the borer was almost always in evidence then:

"(b) Here again the first finding of the pests by Mr. Driver was a matter of chance. It happened that during the usual pier maintenance of a certain pier early in 1931 that Mr. Downing, the Dock Superintendent, saw a section of pile which had been cut off in the plumb posting operations. He cut into the piece and saw a worm. He expressed surprise and asked the job foreman about the bug. The foreman, a Mr. Hendricksen, a Scandanavian, told Mr. Downing that he should have seen the numbers of them he found when making repairs to pier No. 24 in February of this year (1931). The discovery led to Mr. Downing reporting these findings at once to Mr. Driver who ordered an inspection of all the piles of all the piers of his properties.

"(c) Mr. Driver says that the wharf borer works principally in his piers, from the point of pile cut-off downward about 3 ft.

"(d) He states that it is not always necessary for outcroppings of decayed wood to be seen on the outside of the pile. His method of looking for the borers is to cut into any decayed spots seen on the body of the pile or to sound the pile with a light mallet. If the pile sounds unsound or hollow, cuts are made with a hand cutting tool and in many instances, the borer larvae are found.

"(e) Mr. Driver reports that the presence of the larvae from his experience seems not to be in conformance with any cycle. He has found them (larvae) in Feb., March, April, May, June and July. There have been no reports as to these findings in the Winter months.

"Mr. Driver when renewing any borer infected timbers or pile heads, has adopted the policy of replacing with pressure creosoted material. He does not believe painting with creosote to be of any real use. If a pile head is found affected by these borers the policy is to permit the borer activities to progress until the pile has so deteriorated that it must be removed and replaced in the schedule of ordinary maintenance. He feels that the wharf borer only attacks wood in which ordinary decay has started, *but* after the borer has made his home in the pile or timber, the deterioration is very swift. Much more rapid is the destruction than in timbers where decay infection is the sole destructive agent."

From these two reports it appears that the insect is still active. We do not know, however, whether it will attack only wood that is starting to decay or has decayed or whether it will also go into sound wood (untreated) or sound creosoted wood.

Your Committee presents these notes to keep the Association advised and with the suggestion that when wharf structures undergo general repairs that signs of the presence of the borers be looked for. The Committee furthermore requests that anyone who does find evidence, communicate with the Committee so that we may keep the information as to its appearance and behavior up to date.

### Conclusion

Your Committee recommends that this report be accepted as information.

### Appendix F

#### (6) LOSS OF PRESERVATIVE IN TREATED TIES IN TRACK DUE TO USE OF OIL-BURNING WEED DESTROYERS

C. S. Burt, Chairman, Sub-Committee; G. B. Campbell, C. C. Cook, H. R. Duncan, W. R. Goodwin, L. B. Holt, R. S. Hubley, R. P. Hughes, A. J. Loom, L. J. Reiser, T. H. Strate.

Your Committee has continued its investigation and study with reference to the loss of preservative in treated ties due to repeated use of oil-burning weed destroying machines. Previous reports in connection with this study were published in the Proceedings for 1930, pages 751 to 757 inclusive, and in Volume 33, 1932 Proceedings, pages 547 to 549 inclusive. These reports give information in detail concerning experiments that the Committee has undertaken from time to time, however, a brief description of this is repeated here in that these same tests have been continued through the current weed burning season.

Pieces  $2'' \times 8'' - 8'$  were cut from  $6'' \times 8'' - 8'$  thoroughly air seasoned White Oak, Red Oak, Hard Maple, Beech, Sycamore and Southern Yellow Pine ties. One piece was cut from the face side of each tie and the heart center eliminated. These were treated with A.R.E.A. grade 1 distillate oil, 80-20 mixture of grade 1 creosote and coal-tar, and 45-55 mixture of grade 1 creosote and California crude-oil, by the Lowry and Reuping processes, with final retention of preservatives varying from 3 to 10 lbs. per cubic foot of wood. Retention of preservatives was determined by careful weighings of each piece before and after treatment. One piece from each tie was placed in track and subjected to operations of the wood burning machine, whereas the mate to each such piece was placed in adjoining track but not gone over by the weed burner. These pieces that were not subjected to operations of the machine served as a means to determine natural changes occurring during the course of the experiment, such as, change in moisture content and loss of oil by evaporation. All test pieces were carefully weighed before each operation, reweighed immediately afterward and calculations recorded.

The same test pieces have been used for these several different burnings, and charts have been prepared showing complete results of such tests in connection with individual

Remarks: Two pieces cut from each of 20 square sawed Grade 3 ties seasoned 12 months. One piece sawed from each face. One piece from each tie placed in track subjected to operation of weed burner and its mate placed in track not affected by weed burner. Each piece is numbered for identification. Placements will be taken from track and weighed at time of weed burning each year, to determine if there is any difference in loss of weight between pieces subjected to operation of weed burner and those not.

Individual weights on 21 pieces of Southern Pine laid in track to determine loss due to operation of Weed Burner - Size of Pine 8"x8"-8' - Treated with Straight Creosote Oil

| Weight before Treated |              | Weight after Treated |              | Net Gain   |              | Weight Aug. 24, 1931 |              |            |              | Weight Sept. 8, 1931 |              |            |              | Weight Sept. 7, 1932 |              |            |              | Weight (8) Sept. 16, 1932 |              |            |              | Weight July 26, 1933 |              |            |              | Weight Aug. 6, 1933 |              |            |              |

Remarks -----  
 (1) Increase in weight due to rain Sept. 3rd.  
 (2) Part of loss in weight probably due to evaporation of part of water absorbed from rain Sept. 3rd. Weighed 4 to 6 hrs. after 1st weighing before burning.  
 (3) Heavy rain between burning period Sept. 7, 1932 to Sept. 16, 1932.

\*Note - Burner operated in error over these pieces

NOTE - Heavy rain between period July 26th to Aug. 5th.

Pounds

Av. Ht. Not Burned

Av. Wt., Purned

Remarks: Two places cut from each of 20 square sawed Grade 3 ties seasoned 12 months. One place sawed from each face. One place from each tie placed in track subjected to operation of weed burner and its mate placed in track not affected by weed burner. Each place is numbered for identification. Places are all taken from track and weighed at time of weed burning each year, to determine if there is any difference in loss of weight between places subjected to operation of weed burner and those not.

Individual weights of 21 pcs. of Oak laid in track to determine loss  
due to operation of Feed Burner - Size of Oak 2"x8"x8' -  
Treated with - straight Creosote Oil

(1) Increase in weight due to rain Sept. 3rd.

FACTORS -----

- (1) Increase in weight due to rainfall Sept. 1, 1932
- (2) Part of loss in weight probably due to evaporation of part of water absorbed from rain Sept. 3rd. Weighed 4 to 5 hrs. after 1st weighing before burning.
- (3) Heavy rain between burning periods Sept. 7, 1932 to Sept. 16, 1932

NOTE - Heavy rain between period July 26th to Aug. 5th, 1935.

Remarks: Two pieces cut from each of 20 square sawed Grade 3 ties seasoned 12 months. One piece sawed from each face. One piece from each tie placed in track subjected to operation of weed burner and its mate placed in track not affected by weed burner. Each piece is numbered for identification. Pieces are all taken from track and weighed at time of weed burning each year, to determine if there is any difference in loss of weight between pieces subjected to operation of weed burner and those not.

Individual weights of 50 pieces of ties used in test to determine loss of preservative due to operation of wood burning machine. Each piece 2" x 8" x 8', treated with 80-20 mixture Creosote and tar solution, and straight kerosene creosote oil.

Remarks: Two pieces cut from each of 20 square sawed Grade 3 ties seasoned 12 months. One piece sawed from each face. One piece from each tie placed in track subjected to operation of weed burner and its mate placed in track not affected by weed burner. Each piece is numbered for identification. Pieces are all taken from track and weighed at time of weed burning also to determine if there is any difference in loss of weight between pieces subjected to operation of weed burner and those not.

test pieces. (See Exhibits A, B & C). In studying these charts it should be remembered that the figures have to do with test pieces only  $\frac{1}{3}$  the size of Grade 3 ties, and in making final analysis of the situation, these calculations should be applied to the cubical contents of regular  $6 \times 8 - 8'$  ties in each case.

In addition to the tests described in Exhibits A, B & C, similar experiments on a somewhat smaller scale were conducted last year on the Rock Island. While figures regarding these tests are not available at this time, the results of burnings and subsequent weighings show practically no loss of preservative.

It has been suggested there might be a more damaging effect on the section of the tie outside rail, as, heat from the burners seems more intense at these points than it is in the center of the track. To develop information on this question the Rock Island placed two creosoted gum ties (full size ties,  $6 \times 8 - 8'$ ) in track, parallel to the rail at ends of the track ties, and subjected these to operations of the weed burning machine. The results of this test are given below.

|                                  | <i>Weight before<br/>Burning</i> | <i>Weight after<br/>Burning</i> | <i>Loss in<br/>Weight</i> |

Because of the low heat conductivity of wood and the extreme short time of application of the heat, it is the opinion of the Committee that flames from the machine affect only the area of the cross tie near the surface of the face side. Following this thought extractions of creosote were made from two matched test pieces—from one which had been subjected to the weed burning machine 8 different times, and from the other half of the same set which was not burned. Analyses of the oil obtained from these pieces, together with that of the original oil used in treatment are shown below.

| @ 38°C.                                     | @ 38°C.                                      | @ 38°C.                            |

From the above it is noted that there is very little difference in the character of the oil remaining in these particular pieces of the two groups, at this time.

Results of the additional experiments would seem to bear out the opinion of the Committee as expressed in previous reports to the effect that the loss of preservative from treated ties by weight may be considered almost negligible. Attention is also directed to the figures which show an almost equal decrease in weight for pieces which were not subjected to the weed burning machine as compared to those that were burned.

Continued study fails to develop further facts of particular interest and importance relative to the effect of these machines on treated ties in track, but the Committee wishes to again call attention to several observations in this connection, which are given in previous reports on this subject, but which we think are of sufficient importance to be repeated at this time.

It is noted that the effect of weed destroying machines on treated ties, as regards the loss of preservative, diminishes almost directly in proportion to the increase in age of the tie in track. This is particularly applicable to ties of the hardwood group. Ties that have been in service more than three years are rarely affected unless they are mechanically worn or damaged by derailment. Old ties that are so damaged and worn are more often affected by the second burning because the flame is also communicated to the tie from dead burning grass and vegetation. Speed at which machines are operated is governed by the kind and growth of vegetation but at average operating speed the ties are subjected to the heat not more than  $1\frac{1}{2}$  seconds. It is of particular importance that machines be operated at the specified speed. Often, the rate of travel is lower than the speed required to meet conditions and the possibility of damage to the ties in track is thereby increased. This occurs most frequently when burning in yards or on sidings where the vegetation is sometimes much heavier than in main line track.

Untreated ties ignite much more readily than creosoted ties and burn freely, particularly so if they show any splintering from any cause, or if decay has developed. Burning of such ties may be considered beneficial rather than detrimental as the surface chars and destroys incipient fungus growth. As a good many ties do ignite either from the machine or from burning grass and vegetation, it is of utmost importance that section gangs closely follow the machine to extinguish such fires as quickly as possible. Machines should not be allowed to stand in one place immediately after the flame has been shut off as the heat radiating from the apron will damage the ties beneath.

In many cases there seems to be more free oil on the outside of the ties after the weed burner has passed than before, and this adds a protective coating to the tie which probably retards volatilization of the lighter fractions of the preservative and to some extent should prevent checking. The kind of ballast and track dressing has much to do with the effect of these machines on ties, and needless to say the effect is lessened according to the protection provided by the ballast. Much of the failure of treated ties today may be attributed to mechanical wear, and such failure occurs directly under the rail which section is subjected to less heat than any other part of the tie because of the protection provided by the rail base and tie plate.

As already suggested, all experiments thus far along this line seem to indicate that little actual loss of preservatives may be expected from normal operation of weed burning machines. While on the other hand considerable damage to treated ties will follow careless operation of such machines. It is, therefore, strongly urged that every care be exercised to prevent abuse to ties in track because of careless operation of these machines, and that this work be most closely supervised by all concerned.

### Action Recommended

It is recommended that this report be accepted as information and the subject discontinued.

## APPENDIX G

### (7) METHODS OF PROTECTION OF TREATED MATERIALS IN THE FIELD

L. J. Reiser, Chairman, Sub-Committee; C. C. Cook, R. S. Belcher, G. B. Campbell, H. R. Condon, G. M. Cornell, E. A. Craft, W. R. Goodwin, C. W. Greene, R. S. Hubley, R. P. Hughes, G. P. MacLaren, T. H. Strate, W. A. Summerhays, C. M. Taylor.

#### General Statement

#### TIES

In treatment of ties and timber to prevent decay, the life service to be obtained from proper treatment is largely dependent on adherence to definite rules in handling, care, and efficient use. Necessary precautions should, therefore, be observed to obtain maximum life service.

1. Care must be exercised when unloading creosoted ties to avoid fracture and exposing untreated wood. They should not be thrown down high embankments or on rails, rocks, or other materials where they may be splintered or fractured. They should not be removed from cars with sharp pointed or edged tools.

2. "Creosoted ties should be stacked as completely as practicable" (Manual, page 131, Fig. 5 and 6, Committee III) to retard evaporation of the preservative and prevent checking or warpage.

"They should be covered with cinders or dirt wherever exposed to falling sparks." (Manual, page 131, Committee III).

"Ties treated with zinc chloride or other water borne salts should be open stacked as shown in Fig. 1 to 4 inclusive, page 131, Manual, Committee III," and allowed to season as specified.

"Zinc treated ties should be stacked so as to obtain free circulation of air with minimum contact." (Addition to Manual, Bulletin 337, Committee III).

"Ties should be allowed to season and dry for at least 60 days after treating at either treating plant or on the line before being placed in track." (Addition to Manual, page 10, Bulletin 337, Committee III).

"Stored ties of any kind should not be accumulated in groups of stacks without adequate spacing between groups to permit fire control nor without maintenance of bared or plowed ground at least three feet wide around the storage yard wherever fire from adjacent areas may spread." (Manual, page 130, Committee III).

3. Adzed and bored ties must be used with weight of rail for which prepared and spikes must be driven in bored holes regardless of line end. Boring of ties results in increased penetration of preservative surrounding spike area and careless spiking of bored ties should not be permitted.

4. "Ties must be moved with tongs so as to reduce damage incident to handling. Picks, mauls, sledges, and spiking hammers, must not be used in moving ties or placing them in position beneath the rail." (Manual, page 828, Committee XII).

"If ties are driven at all, this should be done with wooden maul. (Manual, page 1277, Committee XVII).

5. Ties split or cracked where bored will cause spike holding power to be greatly impaired. Plugs should not be driven in such defects and spiking continued which will result in further injury to tie. It is, therefore, desirable to vary from standard practice in positioning of spike by reversing position where possible to avoid spiking in crack. Use of plates with four spike slots will facilitate use of most desirable location with ties having such defects.

6. "Where choice has to be made between distributed ties of unequal age, but equal suitability for given trackage, the oldest ties should be used first, providing it is not practicable to determine and use the least durable tie first and to see that no tie is held in storage longer than one-fifth of its estimated life in track." (Manual, page 132, Committee III).

7. "Preserved ties may be destroyed by mechanical action long before it is decayed, and, therefore, should be protected by economical devices when the mechanical life limits the life of the tie." (Manual, page 1273, Committee XVII).

8. "When applying tie plates care should be exercised to see that the plates have a full, even bearing on the ties, that the track is in correct gauge before they are spiked to the tie, and that the shoulder of the plate rests against the base of the rail for the full width of the plate." (Manual, page 831, Committee XII).

9. "Spikes should be started vertically and square and so driven that the face of the spike shall come in contact with the base of rail. The spike should never have to be straightened while being driven," (Manual, page 231, Committee V) "but not driven so far as to cause the neck to bend and/or the head to crack or break off." (Manual, page 831, Committee XII).

Careless driving will result in mutilating fiber around spike hole, contributing to loose spikes with accumulative moisture and infection in untreated wood at center of tie.

10. At locations where it is frequently necessary to clean ashpan, ties should be provided with covers of sheet metal. This covering should rest on furring, providing clearance of not less than one-inch to prevent charring of ties.

11. When making inspection of treated ties in track for renewals, they should not be tested or marked with pick or adze, or other sharp tools which may cut or puncture through to the untreated wood and cause infection and decay in the untreated interior of the tie.

12. Ties which are much checked or split should not be used at joints, as spikes frequently work out from such at this location and require respiking. Excessive spiking shortens life of the tie and care should be exercised that joint ties be of such quality as to insure maximum strength and service.

13. Loose spikes indicate abnormal wear on walls of spike holes, contributing to easy access of water, thereby subjecting such area to decay. All such spikes should be withdrawn and creosoted "tie plugs should be driven to full depth and with the widened head parallel with the tie so as to take up any enlarging of the hole back of the spikes." (Manual, page 132, Committee III).

"Whenever spikes are drawn from ties, creosoted tie plugs must be driven into all holes except in ties which are to be renewed that season. In replacing spikes they must be driven in to the plugs." (Manual, page 828, Committee XII).

Treated tie plugs of standard dimensions should always be available as required to plug holes when respiking as specified, pages 132 and 133 in Manual.

14. Treated ties bruised by derailments but still serviceable at location where damaged may be adzed to remove crushed fibers, such adzed surfaces to be protected by application of hot creosote oil. Ties damaged by derailment or on account of mechanical wear to such extent as to be unserviceable at that location should be salvaged for use in less important trackage or for other uses such as fencing, bulkheading, etc., according to their value.

15. "The Supervisor must frequently inspect ties removed from track to see if any have been removed which might have remained in the track with safety until the next inspection. This report shall be carefully checked by the Division Engineer and where any unusual or unfavorable condition is indicated, a thorough investigation shall be made to insure proper renewals." (Manual, page 827, Committee XII).

16. In relaying of rail and tie plates where adzing of ties is necessary due to wear, ties should be adzed to depth of rail cut or wear in straight line across face parallel with rail, the length adzed to be governed by size of tie plate used. Before adzing all spike holes should be full driven with creosoted plugs and newly adzed surfaces well cleaned and given a thorough application of hot creosote.

17. In disposing of worthless ties by burning, they should be burned at a distance not less than fifteen feet from the nearest end of ties in track, and in case they cannot be piled twenty-five feet therefrom, piles for burning should not consist of more than forty ties. They should not be burned near bridges, telegraph poles, newly creosoted ties, or other treated or combustible materials. Where there is any possibility of fire spreading to adjoining property, it must be carefully watched and kept under control.

18. "For best results it is recommended that certain sections of track be selected on each railroad for the purpose of making accurate tests covering the life of treated and untreated ties of various kinds of timber and various treatments, and that a record be kept of all ties in these sections of track in order to be able thereafter to improve treatment. All ties inserted in such test sections should be marked with dating nails, and, if necessary, with other identification marks." (Manual, page 1273, Committee XVII).

## BRIDGE TIMBER

1. Timber is creosoted to protect it from attacks of fungi which causes decay, and any cutting that exposes the untreated interior is injurious to life of timber and renders it very little better than untreated material.

2. "When ordering treated timber state exact sizes and lengths desired. Cutting treated timber to length in the field shortens its life and should be done only when unavoidable." (Addition to Manual, page 1202, Bulletin 337, Committee XII).

3. "When cutting to length is unavoidable or when necessary to adze or otherwise disturb the surface of treated timber, such surfaces must be swabbed with a liberal quantity of hot preservative followed by two applications of hot sealing compound." (Addition to Manual, Rule 1204, Bulletin 337, Committee XII).

4. "When necessary to bore treated timber in the field, all holes must be treated with hot preservative, followed by sealing compound applied hot, and the bolt immediately driven home." (Addition to Manual, Rule 1205, Bulletin 337, Committee XII).

5. "When unused holes are left in treated timber or piling they must be treated with hot preservative and filled with treated plugs. Before driving the plugs must be dipped in hot sealing compound." (Addition to Manual, page 1206, Bulletin 337, Committee XII).

6. "It is recommended that timber be allowed to season for at least sixty days after treatment. It should be piled with spacer strips to give complete air circulation. In addition to other advantages the fire hazard is greatly reduced when treated material is allowed to season about sixty days after treatment. It has been demonstrated that seasoned creosoted material is more resistant to fire than either seasoned untreated or freshly creosoted material." (Manual, page 1275, Committee XVII).

7. "Creosoted timber piled for seasoning or storage should be sheltered as much as possible from direct rays of the sun. Cross sticks should be placed sufficiently close to prevent long timbers or those of small section from sagging and becoming crooked, and every care should be taken to prevent the checking which exposes untreated wood. The top layers of stacked timbers should be covered with sand or dirt to the depth of not less than one-half inch as protection from the sun, and all grass or rubbish should be cleaned from under and around the stacked material to lessen the danger from fire." (Manual, page 1275, Committee XVII).

8. "Creosoted lumber and particularly long or heavy timbers which have been framed prior to treatment should be stacked with special care to avoid warping or distortion while the material is in storage." (Manual, page 1277, Committee XVII).

9. "In handling treated material, extreme care should be used to avoid damage to the edges of the timbers or breaking through the portions penetrated by the treatment and exposing untreated wood. The use of peavies, canthooks, timber dogs, pickaroons, lug hooks, or other pointed tools on treated lumber should be absolutely prohibited." (Manual, page 1275, Committee XVII).

10. Care should be exercised in the proper placing of creosoted caps to obtain long life or service. If season checks have developed more in one face than in the other, that face should be placed down to prevent infection from moisture entering through such season checks.

11. "Sway braces should be fitted from the bottom and any cutting to length found necessary should be at the top. The cut should then be treated with hot creosote, creosote and bridge cement or roofing pitch and fabric as necessary to protect it from the weather." (Manual, page 1276, Committee XVII).

12. "Where the piles in a bent vary in size or are out of line filler blocks shall be used between the braces and piles, securely fastened and faced to obtain a bearing against all piles. Treated filler blocks shall be used with treated braces." (Addition to Manual, Rule 1214, Bulletin 337, Committee XII).

## PILING

1. Treated piling placed in storage yards should be carefully stacked. Consideration should be given in method of stacking to allow access of water throughout the stacks that fires may be readily extinguished.

2. Piling should be yarded or stored with entire length at rest which prevents sagging and bends, thus eliminating danger from fracture when driven.

3. When stacked on Right of Way at location of bridge, and if not used promptly, they should be stacked in area free of dead grass or other combustible materials.

4. It is necessary that piling be driven to full resistance which insures a finished structure which holds firm in service with no settlement of bents, and it is equally important such driving be accomplished without injury to the material.

5. "The use of dogs may be employed in rafting piles provided these are placed within one foot of the head or four feet of the tip. Rope slings should be used for unloading and handling. Tongs may be used when confined to the ends as outlined above for lifting so that slings may be placed." (Manual, page 1275, Committee XVII). "A sharp pointed tool should not be used to turn a pile in the gins of the driver. This can be done with a spud and sling. Piles should not be bored for staging. For piling driven in water or with the cut off high above the ground, staging clamps may be used. These may be made of two flat bars, bent to semi-circles and bolted together around the pile. A tail turns up at one end of the iron and projects sufficiently to carry the supporting timber on which the staging plank is laid." (Manual, page 1276, Committee XVII).

6. "All treated pile cut offs and chamfered tops where the piles project beyond the caps should be saturated with hot creosote by repeated applications, and then daubed with hot asphaltum or a mixture of creosote and roofing pitch mixed to a vaseline-like consistency, and swabbed in with a long-handled brush. For chamfered tops it is recommended that suitable fabric be embedded in the hot asphaltum, or roofing pitch

and creosote, and that the outside of this fabric be given an additional coating of the waterproofing material." (Manual, page 1276, Committee XVII).

7. "Holes bored for drift pins should be  $\frac{1}{8}$ -inch smaller than the drift. This is not recommended for sway brace bolts, as the thread of the bolt has a tendency to sliver the pile on the opposite side. Where possible holes bored in creosoted material should be filled with hot creosote followed by a mixture of creosote and roofing pitch. After the bolt is driven a portion of the pitch creosote mixture should be placed under the washers at both ends of the bolt which, when the bolt is tightened, gives a water tight job under the washers.

"Pitch can usually be worked in between the timbers before tightening to give further protection. With proper care, decay from sway brace bolt holes can be practically eliminated."

"Any holes that may be made either in top or side surfaces and which are not used should be plugged with treated material. The plug should be dipped in creosote and driven to the bottom of the hole. Holes, abrasions, or checks too large to be plugged should be treated with hot creosote and filled with the mixture of creosote and roofing pitch. This may then be protected by sheet copper held in place with copper nails or by special roofing material laid with the weather side out and coated with the pitch mastic on the outside."

"Bridge crews handling creosoted piling and other creosoted material should keep on hand a supply of creosote, bridge cement, or roofing pitch, saturated fabric, and creosoted shimming and plugging material." (Manual, page 1276, Committee XVII).

8. Treated piling or timbers should not be cut or punctured when inspecting same. When there are indications of decay in interior of piling or timbers, same should be bored, care being taken to swab the holes with preservative and plug same with creosoted plugs.

### TREATED SWITCH TIES

1. The rules recommended for proper protection of cross ties will also apply to switch ties.

2. Care should be taken in ordering switch ties of proper length so that they may be placed in accordance with standard plan and prevent damage to treated wood by cutting back to lengths required.

3. Switch ties located in switches subjected to excessive operation should be of such quality to withstand the severe mechanical wear, especially turnouts in heavy switching yard leads.

### TREATED SIGNAL TIMBER AND TRUNKING

1. All timber should be cut to length and framed prior to treatment because cutting the material after treatment shortens its life. If it is necessary to cut any treated timber, it should be given at least two coats of hot creosote.

2. Trunking and capping treated with creosote or other preservative should be stored under cover whenever practicable to prevent damage by splitting, excessive checking, or warping. If unable to store under cover, it should be close piled and covered with soil to retard evaporation of preservative and warpage of material at top of pile.

### TREATED TELEGRAPH POLES

1. To obtain maximum life service it is necessary to avoid gaining and boring of poles after treatment. They should be gained for cross arms, roofed, if specified, and all necessary holes bored prior to treatment as indicated by standard plan. All gains should be cut accurately and parallel so that cross arms will be in vertical alignment, thus eliminating any necessity of having to regain or bore into the treated wood.

2. After treatment poles should be carefully handled so that treatment is not punctured by grab hooks or fractured by impact. When possible, poles should be unloaded by crane or derrick.

3. All poles should have treatment of sufficient depth so that lineman's climbers will not penetrate through the treated wood which may cause infection and decay.

4. Poles in service should have grass and weeds cleared over sufficient area to prevent burning or damage by excessive heat which would cause creosote to exude from pole when overheated.

5. If necessary that any poles be framed or bored in the field, all newly framed or bored surfaces should be protected with applications of hot creosote.

## Conclusion

Your Committee recommends that this report be received as information and the subject continued with the recommendation to the Committee on Outline of Work that collaboration of Committees III—Ties, VII—Wooden Bridges and Trestles and XVII—Wood Preservation be directed with Committee XII—Rules and Organization to the end that approved rules be published in the Manual under the jurisdiction of Committee XII.

## APPENDIX H

### (8) SERVICE TEST RECORDS OF STRUCTURAL TIMBER INCLUDING PILING

C. C. Cook, Chairman, Sub-Committee; Wm. G. Atwood, R. S. Belcher, G. M. Cornell, E. A. Craft, E. B. Fulks, G. P. MacLaren, F. D. Mattos, L. J. Reiser, Dr. Hermann von Schrenk, T. H. Strate.

In response to circular letter of July 6, 1932, replies were received from 16 railroads listing a total of 100 bridges and trestles with data relating to service life according to the form prescribed by the Sub-Committee.

Replies were received from a total of 32 railroads, the other 16 advising generally that they had but few treated timber structures old enough to give useful record, and had no exceptional data relating to service of untreated structures. Two roads advised they had no permanent timber structures on main tracks.

From the replies there were selected one structure from each railroad as near typical of the experience of the whole number reported for the particular group as could be determined. The groups for which data were requested and are hereafter published, covered timber structures:

- (a) Treated, that have given outstanding service.
- (b) Treated, that have failed or shown serious defects.
- (c) Untreated, that have given outstanding service.
- (d) Untreated, that have failed or shown serious defects.

It is to be recognized that the responding carriers gave data on but a portion of the number of structures existing on their lines,—the number reported ranging from a minimum of one to a maximum of sixteen for individual carriers. The Committee desiring to present data both indicative and relative as to the service of structural timber, treated and untreated, has made further selection for publication purposes, which are considered adequate and representative, at least within the limits of the character of structures indicated by their descriptions.

Naturally all varieties of timbers, their treatments and conditions of their service found in the States and Canada are not covered. However, to the extent that the tables include two or more structures of similar characteristics in respect to these elements, there may be deduced useful and interesting information.

Most notable in the replies received were the preponderating number of treated timber structures reported as giving outstanding service. Where their ages were limited by the comparatively recent use of treated timber, the excellence reported was reflected in the condition which required little if any renewal after a period of years that would have resulted in complete renewal of the structures had they been of untreated material.

Second, in the group of treated structures where failures were recorded, it was generally attributed to failure to give adequate protection to untreated surfaces exposed in field framing of members.

The relatively large number of treated structures giving outstanding service shown in the tables is a reflection of the number of that character included in the reports of the responding carriers.

Specific attention is directed to the three structures of treated timber that showed early failure and to the definite information in respect to the causes which arose from failure to give adequate protection to untreated surfaces exposed by field framing.

There were but five failures in this group of treated timber structures reported; the three quoted in the tables give information representative of the kind of failures and their causes.

Similarly, a limited number of untreated timber structures giving outstanding service were reported. In an additional instance, the responding carrier in stating that the average life of untreated structures (as taken from the record of 15 structures) was found to be nine years, advised further that it was considered economical to use untreated timber. Presumably this arose from the proximity to site and low first cost of the untreated timber.

The tabulations in this group of untreated timber include three structures of woods notably long-lived, viz.,—long leaf yellow pine, oak and redwood. They doubtless were outstanding in their service and it would probably not be inaccurate to say also that they were exceptional. A study of their descriptions as to character of structure, location and probability of delivery of a prime grade of timber at the period of its installation may suggest it.

One other structure of untreated douglas fir located in Northern territory, representative of somewhat similar service of eight structures of the same timber reported by that line, is included. About twenty years' life had been secured from these structures before entire renewal was needed; at that time most of the original timber still was in the structure.

No stress was placed upon indications in the group of "untreated structures that failed or showed serious defects". It was evidently of general acceptance that structures of untreated timber were inferior and were justified only where favorable conditions as to climate, soil, cost, restricted speeds, and other limits of service prevailed. One or more of such structures however, were selected for the tabulations in order to provide relative data as to life and to indicate the limits of their service.

There is shown at the end of the tabulation for each structure, the percentages of certain main members removed and found defective. And, as a matter of concise conclusion, these are summarized as a final figure into percentage of the whole structure removed and found defective.

Such percentages, particularly as relating to the whole structure, were not always completely supplied by the respondents in the form shown. The data, being made available for members, however, could readily and without practical error be translated into a percentage of the whole structure.

This provided at a glance the approximate condition of the structure as it existed as noted in the report. Particularly in respect to treated structures whose life though now well extended to 20 years more or less are without serious or even apparent defect, this information is valuably indicative. It should not, however, be construed as a mathematical representation of the proportions of service life thus far expended. Combined with the history of the particular structure, the data will enable an estimate of probable service life sufficiently accurate for the practical purpose of determining relative economic values.

The extent to which treated timber is used in ballast deck pile trestles and the record as to replacements, including a description of an early renewal account of inade-

quate protection during field framing, is given in the following reply from the Atchison, Topeka and Santa Fe Railway, G. W. Harris, Chief Engineer:

"In 1930, I had an inspection made of a number of ballast deck pile trestles that were built during the period 1899 to 1910. These structures were found to be in excellent condition, and the records show that no repairs had been required on a number of the trestles, including some that had been in service for over twenty-five years, and where repairs had been necessary, the maintenance had been confined mostly to the replacement of caps, ballast curbs and the placing of shore piling.

Bridge 369-A, included in the tables, gives the service record of one of the oldest structures and is typical of the performance of our long service ballast deck timber trestles. The latest bridge inspection shows the need for some minor repairs, but this is to be expected in a structure that has already rendered thirty-three years of service. It is of interest to note that none of the stringers has been replaced to date.

It might be of interest to your Committee to know that as of December 31, 1930, we had in service ballast deck timber trestles aggregating 287,321 single track feet. The renewal of this type has been very limited, the replacements being as follows:

| <i>Cause of Replacement</i>                                    | <i>Number<br/>of Bridges</i> | <i>Average<br/>Age-Years</i> |
|----------------------------------------------------------------|------------------------------|------------------------------|
| 1. Destroyed by fire .....                                     | 9                            | 11                           |
| 2. Washouts, inadequate waterway and lack of penetration ..... | 22                           | 12                           |
| 3. Abandoned—opening filled .....                              | 8                            | 19                           |
| 4. Grade revision .....                                        | 2                            | 22                           |
| 5. Abandoned account line change .....                         | 11                           | 18                           |
| 6. Change in type of structure .....                           | 14                           | 15                           |
| 7. Early failure .....                                         | 19                           | 22                           |

In 1925, when the first replacements were necessary account early failure, I had inspection made of the failed piling and timber, and it was developed that early decay was not due to improper or inadequate treatment, but was caused by abuse of the treated timber when the structures were erected. The history of one of these failures is given in the table of "Structures of Treated Timber Showing Serious Defects or Failed"—Bridge 51-B, and the comments which here follow:

### Reason for Early Failure

Inspection developed that early failure was not due to improper or inadequate treatment but was caused by following construction methods that proved detrimental. Proper care was not exercised in protecting the untreated portion of piling and timber exposed by cutting and boring in the field. The causes of failure of piling were:—

- (1) Decay of the untreated interior of the pile, starting under the cap on account of the cut-offs not being properly protected.
- (2) Cuts made for sway and sash braces in some instances into untreated portion of the timber which were not thoroughly protected with creosote when the gaen was made.
- (3) Decay originating in bolt holes, due to the entrance of moisture; this decay following the fiber of the untreated interior of the pile.

A few years after this trestle was built in 1903, System standard practice was adopted, to coat the tops of piles with hot creosote, two applications of heavy road oil and then cover with a 2-ply sheet of Elaterite, Rubberoid or Paroid roofing fastened with roofing nails, the roofing trimmed to the exact size of the pile. This protection has practically eliminated the type of failure described as Item (1).

The adoption of the use of filler blocks in applying sway and sash bracing has stopped the gaening of piling and failures classified as Item (2) have been overcome.

This inspection developed the necessity of protecting the untreated interior of piling and timber exposed in boring bolt holes, so in 1926 System practice was put into effect of swabbing all bolt holes with several applications of hot creosote. It is thought this treatment will prevent decay, listed as Item (3).

### Failure of Stringers

These were classified as follows:

- (1) Cutting the stringers to required length after treatment.
- (2) Boring of bolt holes without properly treating the exposed untreated timber.

This inspection developed that stringers had decayed at the ends where the timbers were cut to the required length in the field, exposing the untreated wood. The other end of the stringers that had not been cut off were perfectly sound. It is now the practice to cut all stringers that butt on the cap to exact length before treatment and with careful driving and jacking of bents, it is unnecessary to trim any sticks on the ground. This will eliminate failures, Item (1).

As stated above, all bolt holes are now given thorough treatment.

### Failure of Caps

With few exceptions, the caps in the 1903 structure were in excellent condition; those showing decay on account of moisture reaching the untreated interior through bolt holes and checks. All bolt holes are now given careful treatment and this precaution and also the use of larger caps, it is hoped, will overcome the failure of caps."

The oldest large trestle built of creosoted timber of which the Committee received record, is the open deck treated timber trestle, 5.82 miles, on the Southern Railway crossing Lake Pontchartrain. The record for comparative purposes is included in the table of "Structures of Treated Timber giving Outstanding Service". The complete history and record as supplied by B. Herman, Chief Engineer, being of exceptional interest, is quoted below:

| Description:           | Open deck, treated timber trestle. Protected from fire by thin layer of gravel on 1½" untreated cypress plank floor between ties.                                                                                                                                                            |
| Length:                | 5.82 miles.                                                                                                                                                                                                                                                                                  |
| No. of Spans:          | Originally there were 2014—15' spans in the present length of trestle and two 250-ft. swing draw spans. With intermediate bents driven as part of a strengthening program (1927 to 1929) there are now a total of 3267 bents.                                                                |
| No. of Piles per Bent: | Original construction 4, intermediate bents 6.                                                                                                                                                                                                                                               |
| Base Rail to Water:    | Approximately 11 ft.                                                                                                                                                                                                                                                                         |
| Depth of Water:        | 8 ft. to 14 ft.                                                                                                                                                                                                                                                                              |
| Water:                 | Brackish.                                                                                                                                                                                                                                                                                    |
| No. of Tracks:         | Single.                                                                                                                                                                                                                                                                                      |
| Year Built:            | 1883.                                                                                                                                                                                                                                                                                        |
| Timber:                | Treated Pine (except floor).                                                                                                                                                                                                                                                                 |
| Preservative:          | Creosote—from England, designated as High Grade, but specification is not a matter of record. Our best information is that specifications in those days required a specific gravity of not less than 1.03 and at least 40 per cent Naphthalene distilling off between 210 and 235 degrees C. |
| Preframing:            | None.                                                                                                                                                                                                                                                                                        |
| Field Precautions:     | Cut-offs swabbed with creosote and pitch.                                                                                                                                                                                                                                                    |

## PRESENT CONDITION

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Date of Inspection:            | November 17, 1931.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Age of Structure:              | 48 years on inspection date.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Ties:                          | All ties have been renewed—some several times, on account of mechanical wear.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Stringers:                     | Originally 3 ply—7" × 16" under each rail—in 1905 an additional 8" × 16" stringer was placed under each rail to take care of increased loads. Approximately 200 of the original stringers have been replaced account of decay, or approximately 2½ per cent. Present annual rate of renewal is .4 per cent. Stringers taken out for test purposes reveal high strength. Tests in 1928 show no decrease in strength from results of tests made in 1909 and 1912.                                            |
| Piling and Caps:               | Of the 2014 original bents 603 are still in service, approximately 1100 have been cut off and frame bents placed on the stubs and the remainder have two or more piles cut off and frame posts placed on the stubs. Of the 1100 bents with all piles cut off, approximately 325 were rebuilt because of damage by fire in 1885 only two years after the trestle was completed. Caps are replaced principally when piles are cut down although some have been replaced separately due to crushing or decay. |
| Remarks:                       | Stringers are in excellent condition, showing no appreciable decay after 48 years service.<br>Piles are not attacked by marine borers except near the south shore. Piles replaced decayed principally at the cut-off.                                                                                                                                                                                                                                                                                      |
| Percent defective and removed: | Ties .....100 per cent<br>Stringers .....2½ per cent plus or minus<br>Piles ..... 60 per cent " " "<br>Structure Approximately ..... 50 per cent "                                                                                                                                                                                                                                                                                                                                                         |

## Conclusions

The data given in the tables, though necessarily limited by need for conservation of space, is selected as typical of structures of the various kinds of woods and treatment shown and thus as indicative of the service given.

Generally it is evident that creosoted timber trestles give prospect of life two or more times that secured from untreated timber, unless the latter is of timber by nature resistive to decay, or it is in structures where service requirements and climatic effects are moderate or light.

In creosoted timber structures that have shown early failures, the record shows them to have been caused by inadequate protection of surfaces exposed by field cut-offs, borings and destructive handling. Such defects limit the life of creosoted timber irrespective of its kind, whether pine, fir, cedar, oak or other timber of structural grade susceptible of treatment.

Structures of untreated timber are generally not considered to be economic except where light service conditions, nearby supply and low costs prevail.

## Recommendation

Your Committee recommends that the "Conclusions" shown at the end of this report be accepted for publication in the Manual and that the remainder of the report be accepted as information and the subject discontinued.

*To the American Railway Engineering Association:*

Your Committee respectfully presents herewith report covering the following assigned subjects:

- (1) Revision of Manual (Appendix A).
- (2) Extent of adherence to Standard Specifications (Appendix B).
- (3) Substitutes for wooden ties (Appendix C).
- (4) Tie renewal averages and costs per maintained mile, securing data from reports to Interstate Commerce Commission (Appendix D).
- (5) Recommend standard spacing of spike holes for ties pre-adzed and bored for standard rail sections 90-lb. to 131-lb. inclusive, collaborating with Committees IV—Rail, V—Track, and XVII—Wood Preservation (Appendix E).
- (8) A method of predicting tie renewals, including a period of change from untreated to treated ties (Appendix F).
- (9) Type of tie plate best adapted for use with pre-adzed ties, collaborating with Committee V—Track (Appendix G).
- (10) Economy of use of tie plates which are secured to the tie independently of the rail fastenings, with particular reference to the effect on tie life (Appendix H).
- (11) Methods of inspection for renewal of ties, checking thereof, and adherence thereto (Appendix I).

In line with existing instructions, your Committee has elected not to report this year on the following assignments:

- (6) Best practice from the manufacture of the tie to its installation in track, collaborating with Committee XVII—Wood Preservation.
- (7) Economics of the use of ties longer than 8 ft.

### Action Recommended

- (1) That the revisions of the Standard Specification for Cross and Switch-Ties proposed in Appendix A be approved for inclusion in the Manual.
- (2) That the reports contained in Appendices B, C, D, F, G, H and I be received as information.
- (3) That Appendix E be received as information and the subject reassigned by the Board to that committee which is charged with tie plate design.

Respectfully submitted,

THE COMMITTEE ON TIES,  
W. J. BURTON, *Chairman.*

## Appendix A

## (1) REVISION OF MANUAL

Specification for Cross-Ties  
Specification for Switch-Ties

John Foley, Chairman, Sub-Committee; R. S. Belcher, H. R. Duncan, C. F. Ford, R. M. Jolley, L. T. Nuckols, S. S. Roberts, J. W. Tate, Sverre Thorvaldson.

Difficulties in the applications of the specifications for cross-ties and switch-ties which were anticipated during the discussion of standards ten years ago have not developed to the extent expected. Experience with tie procurement since the standards were adopted in 1926 has shown that the compromises with engineering requirements agreed to then are no longer necessary. Gradually more and more railroads have individually strengthened their specifications by lowering the manufacturing tolerances as the standard of tie produced has been raised generally.

Since the adherence of the railroads to the standards encouraged the manufacturers of ties to apply more careful and skillful workmanship to his product and to take pride in his output, the appropriateness of desirable changes in the specifications is apparent, and the following revisions of the Manual are recommended for the reasons given below:

SPECIFICATION FOR CROSS-TIES (Manual, page 119)

SPECIFICATION FOR SWITCH-TIES (Manual, page 124)

| <i>Present Form</i>                                                                                                                     | <i>Proposed Form</i>                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Split</b>                                                                                                                            | <b>Split</b>                                                                                                                                      |
| 16. One which is not more than 10 inches long will be allowed, provided a satisfactory anti-splitting device has been properly applied. | 16. One which is not more than 5 inches long will be allowed, provided sufficient satisfactory anti-splitting devices have been properly applied. |

Whatever split is present in an accepted tie may be expected to extend farther under the stresses of seasoning and traffic. Consequently the acceptance of a split already long enough (in an 8-ft. tie) to reach into the section requiring maximum strength for spiking plates and rails has been poor practice. Under improved manufacturing practice, ties with excessive splits are no longer common, and the tolerance of a split longer than 5 inches is not now advisable.

A single anti-splitting device in an end of a split tie is not always enough to stop its rending. Depending on the kind of wood, size of tie, location of pitch, and other factors, effective arresting of splitting may require two or more irons. The wording of the specification needed changing to permit insistence on enough irons to save the tie.

SPECIFICATION FOR CROSS-TIES (Manual, page 119)

| <i>Present Form</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <i>Proposed Form</i>                                                                                                                                                            |

| <b>Dimensions</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>Dimensions</b>                                                                                                                                                               |
| 20. The lengths, thicknesses and widths specified will be considered met by ties 1 inch shorter, and $\frac{1}{4}$ inch thinner and narrower than the standard sizes. Ties over 1 inch, but not over 2 inches, more in thickness than the maximum ordered will be accepted as one size below the largest tie ordered. Those over 2 inches more in thickness; those over 3 inches more in width; or those over 2 more in length than the maximum ordered will be rejected. | 20. The lengths, thicknesses and widths specified are minima for the standard sizes. Ties over 1 inch longer, thicker or wider than the standard size ordered will be rejected. |

## SPECIFICATION FOR SWITCH-TIES (Manual, page 124)

*Present Form***Dimensions**

20. The lengths, thicknesses and widths specified will be considered met by ties 1 inch shorter and  $\frac{1}{4}$  inch thinner and narrower than the standard sizes. Ties over 1 inch more in thickness, over 3 inches more in width, or over 2 inches more in length than the maximum ordered will be rejected.

*Proposed Form***Dimensions**

20. The lengths, thicknesses and widths specified are minima for the standard sizes. Ties over 1 inch longer, thicker or wider than the standard size ordered will be rejected.

Carelessness alone is responsible for the production of ties shorter than the standard lengths of 8 ft. and 8 ft. 6 in. Since studies of track stresses indicate that ties could advantageously be longer than the present standards, there is solid reason for ceasing to tolerate manufacture which is below normal in regard for good workmanship.

The allowance of  $\frac{1}{4}$  inch which provided for average axmanship and was designed to cover the occasional thin or narrow hewed tie has been used by millmen to justify 100 per cent production of ties with thicknesses and/or width less than the nominal standard thickness.

Now that the majority of ties are given preservative treatment and many of them are adzed, it is more than ever essential that reduction of the standard thicknesses should not be tolerated. The latter shrink anyhow as a result of seasoning preparatory to treatment.

The five standard widths of ties provide for the utilization of all the normal diameters of logs which yield the two standard thicknesses. With a difference of only 1 inch between each successive standard size, a tie now wide enough for one size automatically falls into the next lower size. Since such a tie (within the range of standard widths, but too narrow for a given size) is now thereby rejectable altogether, there is no longer excuse for tolerating a reduction in its width, which is too often deliberate.

The cross-cutting of a tie 6 inches to 10 inches in thickness or width does not require a leeway of 2 inches under the improved manufacturing which now prevails; 1 inch of overlength is ample for careful choppers or sawyers aiming to produce ties with square ends.

The round ties which constitute the class catered to by the admission of 3 inches wider than the maximum standard are expensive in many ways after their acceptance; they occupy valuable car space when shipped, require more freight to be paid, split more while seasoning than narrower ties with less sapwood to shrink, reduce the number of ties handled at one time in teating cylinders, absorb excessive quantities of preservative, and disturb ballast unduly when inserted in track. Closer utilization of logs has greatly reduced the number of such ties produced, and the curtailment of the tolerance in width to 1 inch will be contribution to the conservation of timber.

The recommended revisions of the Specification for Cross-ties necessitate corresponding changes in the illustrations of the "Application of the Specification for Cross-ties (Manual, page 121). In line 4, column 5, the thickness becomes 82 instead of 8"-9" and the bottom width 9"-12" instead of 9"-15"; column 6, the thickness 8" instead of 9". In line 5, column 6, the width becomes 10" instead of 12".

## Appendix B

## (2) EXTENT OF ADHERENCE TO STANDARD SPECIFICATIONS

John Foley, Chairman, Sub-Committee; R. S. Belcher, Doyle Campbell, H. R. Duncan, C. F. Ford, R. M. Jolley, L. T. Nuckols, S. S. Roberts, J. W. Tate, Sverre Thorvaldson.

During 1933 the consumption and production of ties continued subnormal. The comparatively few railroads accepting freshly-made ties were free from any pressure to depart from the standard specifications, judging by the reports from individual members of the Committee on Ties, who found stocks being replenished with excellent ties wherever they observed them.

The available statistics on the number of cross-ties in the hands of producers show that during the past year they have stocked as many as they have shipped. It is to be hoped that this balance between demand and production can be maintained. Were a situation to develop wherein the requirements of the railroads drained quickly the relatively short supply of stored ties and production did not keep pace with consumption, care should be exercised to see that the improvement in the dimensions and quality of ties due to the application of the standard specifications is not lost as a result of competition for supplies by railroads on the basis of inspection. After the demonstration during the past decade of what can be accomplished by a single standard adhered to with reasonable uniformity, it would be deplorable for railroads to resume the former practice by many of meeting competition in procurement through lowering the quality and size of ties accepted. Competition by means of inspection instead of price does not increase the supply of ties; it induces the producer to overlook slipshod manufacture and thus encourages the making of sub-standard ties. For one railroad to accept as Size 3 a tie which is Size 2 or to accept as sound or solid a tie which is decayed or split in order to appear to be paying a like or lower price seems a senseless procedure, but it was for a long time customary performance whenever the demand for ties exceeded the supply, and the subject is brought up in the hope that history will not repeat itself. There are sufficient sizes of standard ties to permit the railroad desiring to economize to purchase the cheaper smaller sizes. The debauching of inspection is started by the railroads; it is not sought by the producer, for he knows from past experience that its only result is the demoralization of his industry.

In a paper on "Why Close Adherence to Standard Specifications Pays from the Producers' Standpoint", read at the 1933 annual meeting of the Railway Tie Association, its author says: "Still another benefit to be derived by the producer is by holding strictly to the specifications as regards size. If the inspector is tolerant, even to a small degree, and permits ties of undersize to get into the higher size, then the producer will become careless in the manufacture of his timber and will in many instances cut some timber and take a chance; whereas, if he understands that close adherence to specifications regarding sizes will be applied, he will not denude his timberland and will cut only such trees as will work without waste. I might say that the producer and consumer are alike indebted for standard specifications, because of the benefits each derives therefrom, but dealing more directly with the producer, his slogan—similar to that of our good friends, the railroads—might well be 'Stop-Look-Heed' strictly the standard tie specifications, for an 'honest tie is the best policy'".

| Kind of traffic     | High speed, heavy service, freight and passenger |

\* Changed from 85-lb. rail in 1930.

Four ties removed May, 1933, account of breaking up and disintegration of concrete under rail seat. When removed, all found to be broken and held together only by the reinforcement. Inspection July, 1933, showed the 63 in track all in good condition except three or four. These showed slight cracking and disintegration under rail seat and will probably have to come out within a year.

## Bessemer &amp; Lake Erie Railroad

Reported by F. R. Layng, Chief Engineer

Date—August 2, 1933

| Location            | Springfield, Mo.                   |
| Date put in track   | December, 1914                     |
| Number put in track | 125                                |
| Number now in track | 90                                 |
| Kind of ballast     | Cinders, gravel, chatts            |
| Weight of rail      | 85-lb.                             |
| Kind of traffic     | Heavy service, exclusively freight |

The ties are getting very badly corroded and the lugs holding the wooden fillers are pretty weak and in some instances are broken off. Thirty ties were removed during last year on account of complete failure of lugs holding wooden fillers in place.

### Southern Pacific Lines

Reported by E. A. Craft, Engineer Maintenance of Way

Date—August 21, 1933

|                     |                           |
|---------------------|---------------------------|
| Name of tie         | U. S. Indestructible      |
| Location            | Eagle Pass, Tex.          |
| Date put in track   | 1916                      |
| Number put in track | 23                        |
| Number now in track | 22                        |
| Kind of ballast     | Cinder                    |
| Weight of rail      | 80-lb.                    |
| Kind of traffic     | Main track, light service |

Original spiking blocks have been removed, account decay, and have been replaced by blocks made from creosoted ties.

### Terminal Railroad Association of St. Louis

Reported by H. J. Pfeifer, Chief Engineer

Date—August 10, 1933

|                     |                                                              |
|---------------------|--------------------------------------------------------------|
| Name of tie         | Miller                                                       |
| Location            | St. Louis, Mo.                                               |
| Date put in track   | May, 1924                                                    |
| Number put in track | 100                                                          |
| Number now in track | 100                                                          |
| Kind of ballast     | Cinder                                                       |
| Weight of rail      | 100-lb.                                                      |
| Kind of traffic     | Moderately heavy freight and passenger service, medium speed |

Ties are in first-class condition, none of them have been removed and no expense of any kind has been incurred in connection with them since installed. Judging by present condition, there is every reason to expect a life of thirty years or more.

Col. 3 derived by dividing Col. 3 Table A by Col. 2 of same table.

Col. 4 is total of columns 2 and 4 of Table A.

Col. 5 derived by dividing the totals of columns 2 and 4 of Table A, by Col. 8 of same table.

Col. 6 is weighted average of costs shown in columns 1 and 5 of Table A.

NOTE: Compiled from Annual Reports of Class I Steam Roads to the Interstate Commerce Commission.

NOTE: Statement applies to Class I roads and includes consolidated data for Class I Roads merged during the period 1928 to 1932, as follows:

Alabama &amp; Ohio - includes efforts, Rochester &amp; Pittsburgh and efforts, a Suckewanna.

Grand Truck Western - includes Chicago, Detroit &amp; Canada Grand Truck Junction and the Detroit, Grand Haven &amp; Alameda.

New York Central - includes New York, Indianapolis &amp; Terre Haute; Cincinnati Northern; Cleveland, Cincinnati, Chicago &amp; St. Louis;

Michigan Central and Ohio Delaware.

Pennsylvania - includes Lake Erie &amp; Seashore.

Reading Company - includes Perkasie and the Port Reading.

Crescent &amp; Ohio - includes Hoising Valley.

Louisville &amp; Nashville - includes Louisville, Henderson &amp; St. Louis.

Duluth, Wabasha &amp; Northern - includes Duluth &amp; Iron Range.

Atchison, Topeka &amp; Santa Fe - includes Kansas City, Mexico &amp; Orient.

Panhandle &amp; Santa Fe - includes Kansas City, Mexico &amp; Orient of Texas.

Louisiana &amp; Arkansas - includes Louisiana Railway &amp; Navigation Company.

a Not Class I road prior to 1932.

b Estimated total cross ties in all maintained track not available.

c Not a Class I road prior to 1929.

d Not a Class I road prior to 1930.

Bureau of Railway Economics

Washington, D.C.

June, 1933.

## Appendix D

## (4) TIE RENEWALS AVERAGES PER MILE MAINTAINED

W. J. Burton, Chairman, Sub-Committee; S. B. Clement, S. S. Roberts.

Because of requests for earlier publication of its tie renewal statistics, your Committee made a preliminary report on this subject which was published on page 71 of Bulletin 356 of June, 1933. This preliminary report included all data for United States railroads but did not include data for the three principal Canadian railroads because the latter was not then available. The Canadian data is given herewith in the form established by your Committee.

It is hoped that future reports, including the Canadian data, may be published not later than in the June Bulletin.

TABLE A

## GROSS TIES LAID IN REPLACEMENT - CANADIAN RAILS

Calendar Year Ended December 31, 1932

| Road                       | Wooden ties untreated (U) |              | Wooden ties treated (T) |              | Ties other than wood (S) |              | Total ties maintained and second hand applied (item 24) | Estimated total cross ties in all tracks maintained (item 25) | Equivalent gross ton-miles $\frac{A}{B}$ |

## Appendix E

## (5) RECOMMEND STANDARD SPACING OF SPIKE HOLES FOR TIES PRE-ADZED AND BORED FOR STANDARD RAIL SECTIONS 90-LB. TO 131-LB., INCLUSIVE, COLLABORATING WITH COMMITTEES IV, V AND XVII

E. E. Chapman, Chairman, Sub-Committee; H. F. Brown, R. E. Butler, H. R. Clarke, C. F. Ford, C. W. Greene, R. M. Jolley, C. S. Kirkpatrick, F. C. Krell, L. T. Nuckols, S. E. Shoup, L. L. Tallyn and J. W. Tate.

In 1933 the Railway Tie Association presented a request to the American Railway Engineering Association that consideration be given to so standardizing track and its parts for the more important rail sections as to result in standardized adzing and boring of ties.

The advantages for the tie producer were shown to be as follows:

"1. Regular and fairly uniform production of cross-ties is greatly to be preferred over intermittent production with slack periods followed by rush periods. The reasons are so patent that recital is almost superfluous. The best ties are those made by professional tie makers. Such men must be given fairly regular employment in order that they may live and remain in the producing territory. The expense of retaining tie makers during dull periods is a cost which must be not only borne by the producer but passed along to the user.

"Whether used treated or untreated, ties should be properly seasoned, which takes from two to twelve or more months; so that it is desirable for the producer to anticipate the demand and to manufacture some ties prior to specific orders. Such early production tends to care for the tie makers during dull periods, as well as smooth off the production peaks. The latter usually results in price competition but in little or no additional total production of good ties.

"The standard specifications for ties and their preservative treatment went a long way towards enabling the producer to get out ties between the seasons of active purchasing because the producer knew that if his ties met the specification he could find a buyer and that if impregnation became necessary before the ties were sold, he could give a standard treatment and still be reasonably sure of a sale.

"But the new and growing practice of pre-adzing and pre-boring has taken away part of the benefit from standard specifications and made it much less possible to treat ties prior to specific orders, on account of the great variation in the required spacing and arrangement of the spike holes. No two railroads specify the same pattern, even for identical rail sections, cant of tie plates, etc., with the result that if a producer makes ties without orders, and it becomes necessary to treat such ties, they must be either treated without boring, or bored to some template which will very likely be unsatisfactory to many later prospective buyers.

"Wood preserving plants can also operate to best advantage under fairly uniform demand instead of intermittent demand, dull, and rush periods.

"The treating plants also would benefit from standard machining because of the reduction in the number of necessary templates, knives and bits, and in the labor of making changes to accommodate different patterns of adzing and boring.

"Any reduction in the number of such patterns through standardization is therefore desirable from the standpoints of both producer and treater, even though a single standard is not possible."

The advantages for the railroads were stated to be as follows:

"2. In the long run, all producer costs must be borne by the purchaser. A corollary is also true, i.e., in the long run what benefits the producer will benefit the purchaser. This is only another way of stating the old familiar law of 'Supply and demand'. Increase the supply, or lower the cost, and the price (with a given demand) will tend downwards.

"Removal or lessening of the peak demands for ties will tend to ease those wasteful buying periods which have always come when business 'opens up.'

"Simplification and standardization of adzing and boring will also benefit railroads through the reduction in stocks and the greater flexibility and ease of distribution of their ties, just as similar standardizations of other materials have been of benefit.

"The smaller roads may purchase standard adzed, bored and treated ties, knowing that what is furnished will exactly fit their needs. While the larger roads may prefer to buy their ties before treatment, and to carry them during the seasoning period, the opportunity for the smaller roads to buy standard adzed, bored and treated ties will react to benefit both the small and the large roads.

"The opportunity for the advance producer to treat ties as soon as they are sufficiently seasoned should remove the tendency to hold unsold ties too long before giving preservative treatment, with the resulting (but frequently unobservable) deterioration and lessened service life. Even though the smaller roads were the only ones to purchase black ties, the benefit from longer service for their ties would react to lessen the total demand for ties and thus benefit the larger roads as well.

"An almost complete lack of agreement in the specified dimensions, even for the same rail sections, tie plate cant, etc., is to be noted. The very small differences in many cases indicate what happens when separate men work independently on the same problem and they furnish a good example of the desirability of the preparation of standards at the time a new practice is being introduced."

The results secured from the questionnaire sent out by the Railway Tie Association committee are shown by Exhibit A and substantiate the statement regarding the radical lack of agreement on spacing bored holes and adzing ties.

In order to bring out this lack of agreement graphically, the locations of holes in ties and the lengths of adzed surfaces for two rail sections have been plotted. These are the 110-lb. R.E. and 130-lb. R.E. rail sections (see Exhibit B).

The causes for differences of spacing holes and adzing of ties are as follows:

1. Design of rail:

- (a) Width of base.
- (b) Width of head.
- (c) Height of rail where canted tie plates are used.

2. Design of tie plate:

(a) Canting:

There are different cants in use as follows:

- (1) Flat
- (2) 1 in. in 44 in.
- (3) 1 in. in 40 in.
- (4) 1 in. in 38.8 in.
- (5) 1 in. in 24 in.
- (6) 1 in. in 20 in.

The A.R.A. standard coning of car and locomotive wheels is 1 in 20. One railway maintains 1 in 38 and one 1 in 16.

(b) Length and eccentricity of tie plate:

Various railroads use tie plate designed for ties made of hard or softwood, heavy or light loads, and perhaps for other variables.

(c) Varied locations of spike holes due to design by different individuals:

The graphs show the radically different locations for the same rail sections used by different companies.

(d) Location of V ribs in bottom of tie plates:

The general recommended design for tie plates as shown by 1929 A.R.E.A. Manual is as follows:

"TABLE OF DIMENSIONS FOR TIE PLATES, INCHES

| Length<br>of<br>plates | Range of<br>rail bases             | Same for flat and<br>canted plates |                 |               | Flat<br>plates<br>D & E | Canted<br>1 in 40 |               | Canted<br>1 in 20 |               |

## "DATA FOR DESIGNING TIE PLATES

Ribs not exceeding  $\frac{1}{4}$  in. deep are desirable on bottom of plate.

Thicknesses shown are exclusive of any ribs or corrugations on bottom.

On hardwood ties, widths of 7 in. or  $7\frac{1}{2}$  in. are recommended.

If splices are slotted for spiking, spike holes in tie plates shall be located accordingly.

Spike holes shall be made the size of the spike plus  $\frac{1}{8}$  in., and in high carbon hot worked plates, spike holes shall have a fillet radius of  $\frac{1}{16}$  in.

Plates may be rolled with a camber or crown of  $\frac{1}{16}$  in. if desired by the purchaser.

Where plate is cambered or crowned the shoulder height,  $\frac{5}{16}$  in. is measured at center of plate.

For extra heavy service add  $\frac{1}{8}$  in. to dimensions D and E."

### 3. Design of Spikes:

The standard spikes shown on page 254 of 1929 Manual are  $\frac{1}{8}$  in. and  $\frac{5}{8}$  in. square. Spikes with thickened shanks for the portion above tie (to combat neck grooving) are in use. Some screw spikes are also in service.

The standard spike sizes should not cause any trouble due to small difference in section.

### 4. Design of joint bars:

The designs of joint bars are so varied that each section has to be considered separately. The present trend is to standardize on joint bars in which the bottom toes do not protrude beyond the base of the rail. Standard bolt spacing will assist in a standard for pre-boring.

### 5. Ties:

The Standard Cross-ties, as shown on page 118 of A.R.E.A. 1929 Manual, are given below:

| Size | Sawed or Hewed Top, Bottom, and Sides | Sawed or Hewed Top and Bottom     |
|------|---------------------------------------|-----------------------------------|
| 1    |                                       | 6 in. thick by 6 in. wide on top  |
| 2    | 6 in. thick by 7 in. wide on top      | 6 in. thick by 7 in. wide on top  |
| 3    | 6 in. thick by 8 in. wide on top      | 6 in. thick by 8 in. wide on top  |
|      |                                       | 7 in. thick by 7 in. wide on top* |
| 4    | 7 in. thick by 8 in. wide on top      | 7 in. thick by 8 in. wide on top  |
| 5    | 7 in. thick by 9 in. wide on top      | 7 in. thick by 9 in. wide on top  |
| 6    | 7 in. thick by 10 in. wide on top     | 7 in. thick by 10 in. wide on top |

The standard sizes in general use are 1, 2, 3, 3A, 4 and 5.

## DISCUSSION

There are only about twenty creosoting plants owned and operated by about ten railroads in the United States. Other railroads obtain their treatment at commercial plants. These few railroads who treat part or all of their own ties produce a very small portion of the ties treated each year, so that standardizing of the boring and adzing of ties is important to most railroads and to a large part of the total treated tie production.

A table has been prepared showing what may possibly be accomplished if recommended standards of the Manual are followed. If the present standards were adhered to,

\* Railways which specify both 6 in.  $\times$  8 in. and 7 in.  $\times$  7 in. ties manufactured on top and bottom only and which desire to separate the 6 in. from the 7 in. ties will designate the 7 in.  $\times$  7 in. as Size 3A.

it would be possible to adze all ties with a 12.5 in. adzing length and this would care for present A.R.E.A. standards as to length of tie plates. In order to meet sizes of tie plates in use, or likely, the adzing space should be 16 in. in length, with 9 in. to the outside and 7 in. to the inside of the rail center to care for eccentricity of plates.

The report of the Special Committee on Stresses in Railroad Track of 1925 indicates that on tangent track plates sink down into the ties more on the inside of rail than on the outside, with a tendency for the gage of the track to tighten. On curved track the opposite is the rule. This was checked with both the flat tie plates and the plates which had a cant of 1 in 20. The recommendation of the Special Committee on Stresses in Track was that the eccentricity of tie plates should not be over about  $\frac{3}{8}$ -in.

It will be noted from the graphs for 110-lb. R.E. and 130-lb. R.E. rail sections that there are radically different locations for spike holes across the width of the plates, and that also some roads are using three spikes on both the outside and the inside of the rail while others use three spikes on the outside and two on the inside of the rail. Also, that where four spikes per tie plate are used, there are variations in spacing of from  $1\frac{3}{4}$  to  $4\frac{1}{2}$  in. Consideration should be given to a standard distance between the spike holes at each edge of the rail base. This dimension may depend upon the bolt spacing of the rail joint. A good distance from the standpoint of the tie would be 3 in. or  $3\frac{1}{2}$  in.

In the following tabulation pertinent dimensions are given for adzing to meet the existing standards of the Association. However, a single standard of adzing for all rail sections is recommended.

| Weight<br>of<br>rail | Dimensions<br>of rail, in. |        | Distance between center lines<br>of rails at base, ft.-in. |            |            | Maximum length<br>outside of tie<br>plates, ft.-in. |
|----------------------|----------------------------|--------|------------------------------------------------------------|------------|------------|-----------------------------------------------------|

### Recommendations

In view of the interdependence between rail joint and tie plate design and the fact that as far as the tie is concerned, the standard for pre-boring and adzing can be made to conform to the design requirements for joints and tie plates, your Committee respectfully suggests that this subject be reassigned to the proper committee, with instructions to consider the following suggestions in preparing a standard or standards of tie plates which will result in standardized adzing and boring:

1. A single standard of cant.
2. A standard distance between centers of spike holes in all tie plates at the edges of the rail base.
3. The lengths and eccentricity of tie plates to be standardized.
4. A standardized location for the grooves cut in the cross-ties, both as to distance between the two grooves under each rail and the distance (gage) between the grooves under one rail and those under the other rail so that all cross-ties may be pre-grooved to a single standard regardless of the rail section to be used, making the necessary accommodations for different rail sections in the designs of the tie plates for different rail sections.
5. To particularly expedite standards for plates and boring for the new 112-lb. and 131-lb. rail sections.

Data for rail sections lighter than 90# is not given. There is fully as much lack of standardization with the lighter sections as is indicated above for the heavier sections.

#### Explanation of References

Dimension A is distance across width of tie between centers of spike holes at the edge of rail base.

Dimension B is distance along length of tie between centers of spike holes at the edge of rail base.

Dimension C is distance along length of tie between the centers of inside spike holes at the two rails.

Dimension D is the length of adzed surface.

The patterns referred to are as follows:

**(8) A METHOD OF PREDICTING TIE RENEWALS, INCLUDING A PERIOD OF CHANGE FROM UNTREATED TO TREATED TIES**

E. L. Crugar, Chairman, Sub-Committee; John Foley, W. C. Bolin, H. F. Brown, C. S. Kirkpatrick, A. F. Maischaider, L. J. Riegler, S. S. Roberts, S. E. Shoup, W. W. Wysor.

The method of predicting tie renewals as outlined in the following report is not new, but an attempt has been made to simplify the procedure by the use of tables.

The renewal rates as set up in the report are based on data available on the performance of untreated and zinc-chloride treated ties.

Cross-ties inserted during the past several years on most roads have been treated by ways and means which are considered improvements over earlier practices, and it is reasonable to expect that these improvements will bring about a material increase in the average life of ties. In addition to the methods of treatment to stop natural deterioration of ties, improvements have been made in design of the track structure bringing about a further increase in the average life by reducing mechanical wear. The necessary information is not at present available which will give an indication of the manner in which the ties, with the improved treatment and better protection, will fail or the rate at which they will require replacement. It has therefore been necessary to make assumptions as to their performance.

**DEFINITIONS OF TERMS**

**TIE-YEARS.**—This term is used to indicate the unit of service produced by one tie in track one year. One tie in track 10 years produces 10 tie-years; two ties in track 5 years produce 10 tie-years, etc.

**AVERAGE LIFE.**—The average life of a group of ties is found by dividing the total tie-years produced by the individual ties, by the total ties in the group.

**NORMAL ANNUAL RENEWALS.**—Normal annual renewals is the number of ties required annually to maintain the track without a change in standard of maintenance.

**UNIFORM ANNUAL RENEWALS.**—This term refers to the renewals in any one year after the group of ties has been in service long enough to produce a condition whereby the renewals become the same for every year. This value is always equal to the number of ties in service, divided by the average life.

**LIFE OF TIE.**—The life of a tie as used herein is the number of years between the end of the year during which it was inserted and the end of the year during which it was removed.

**AGE INTERVAL.**—The age interval used is one year, taken from the end of one year to the end of the following year.

**7-YEAR TIES (8-YEAR TIES, ETC.).**—This term is used for convenience to indicate a group of ties having an average life of 7 years, etc.

**7-YEAR TIE (8-YEAR TIE, ETC.).**—This term is used for convenience to indicate a tie in a group of ties having an average life of 7 years. The term is hypothetical and does not mean that the life of the individual tie is 7 years.

**GENERAL DISCUSSION OF RENEWAL PREDICTIONS**

Tie renewals for any year can be predicted, when sufficient data are available, by calculating the number of ties in track which will be removed during that year. Such a prediction when based on actual records of past renewals is of value for checking the number of ties requested on the basis of field inspection. Within practical limits the prediction can be used in making purchases of ties for future requirements.

Studies of tie renewals have been made since the early part of the twentieth century in an effort to establish the law of probability governing the rate of failure, and these have changed the old conceptions as to the order in which ties fail. They have also shown that the rates of failure in different classes are similar when compared to the average lives of the ties in the groups.

Renewals are studied by dividing ties into groups of similar kinds or classes. A renewal curve is developed by reducing the number of ties removed annually to a per cent of the total in the group. This curve is more easily visualized when it is shown graphically as in Fig. 6, which is a comparison of the accumulated renewals for groups having average lives of 8, 12, 16, 20, and 24 years.

Sufficient data are available to show that the only difference between untreated and treated ties in connection with making a renewal prediction is the difference in their average lives.

**RENEWAL CYCLES.**—To illustrate how tie renewals fluctuate from year to year in definite cycles, the two curves shown in Fig. 1 were plotted from a prediction of renewals on two sections of track, each constructed with 1,000,000 ties. On one section the renewals were made continuously with 7-year untreated ties, and on the other with 24-year treated ties. If renewals are predicted for a long enough period of time, they will eventually become uniform as shown in Fig. 1. In connection with this illustration, it is interesting to note that during the first fifty years after date of construction, 6,744,738 7-year ties and only 1,632,904 24-year ties were used for renewals.

**EFFECT OF CHANGE IN CLASS OF TIES.**—To illustrate the theoretical effect of a change from the use of untreated to treated ties, it was assumed that the section of track constructed with 7-year ties as referred to in the preceding example was maintained with 7-year ties for 19 years, and that after that time all renewals were made with 24-year treated ties. The effect of this change is shown in Fig. 2. The oscillations of the renewal curve continue until eventually it reaches a uniform renewal line.

**RENEWAL PREDICTION.**—Fig. 3 illustrates a prediction on a road where it was known there were 1,241,149 ties in track at the end of 1931. The ties in track on this road were untreated and zinc-chloride and creosote treated. The average life of the creosoted ties inserted prior to 1931 was estimated at 18 years. Beginning with 1932, all ties were pre-adzed and bored and were given a heavier treatment, and for these reasons the estimated average life was increased to 23 years. The calculations were made by working out the renewals of the four classes separately, using the actual renewal figures prior to 1932 and the calculated figures beginning with the year 1932. The smoothness of the prediction curves as shown in Fig. 1 and 2 is lost to some extent in the actual prediction curve due to the mixture of the four classes of ties.

Since treated ties are being used on this road, the theoretical effect on renewals by a change to the use of untreated ties is shown by the dashed line. It was assumed that renewals were made from 1932 to 1938 with the 23-year treated ties and from that time on with 8-year untreated ties. While this prediction is in the reverse order of the problem assigned to the Committee, it shows clearly the result which could be expected if a change were made from the use of treated ties with a long average life to untreated ties with a short average life.

**COMPARISONS OF TIES RENEWED PER MILE.**—For a number of years records have been published showing the ties renewed annually per mile on various roads. All we know from these records is that some roads use more ties per mile than others. A comparison of renewals per mile on two roads does not show the existing tie conditions. The only way this can be shown is by a comparison of the renewal predictions. Fig. 4 illustrates, in theory, renewal predictions on two roads. During the year 1932, Road A

FIG. 1.—Illustration of predictions of tie renewals on two sections of track, one constructed and maintained with 7-year ties and the other one with 24-year ties.

used 179 ties per mile, while Road B used only 101 ties per mile. Each road had the same number of ties in track and had been using the same class of ties, but Road B had started the use of the longer life treated ties several years prior to Road A so that the renewal cycles were not the same. If a comparison of the ties renewed per mile on these two roads were made without the prediction curves, it would lead to erroneous conclusions.

FIG. 2.—Illustration of the effect on renewals required if a change from 7-year ties shown in Fig. 1 is made to 24-year ties at the beginning of the 20th year.

**DEFERRED MAINTENANCE.**—Without the use of a prediction of renewals it is possible to make a comparison which does not reflect the true conditions of maintenance. To illustrate this, assume that the prediction shown by the solid line in Fig. 3 has been equalled in actual practice. During the three years 1950, 1951, and 1952, 127,143 ties were renewed. If this three-year period is compared with the record for the three years 1943, 1944 and 1945, during which time 211,539 ties were renewed, there would appear to be deferred maintenance during 1950, 1951, and 1952 to the extent of 84,396 ties. Actually the lower renewals during the latter years were due to the normal fluctuations of the renewals rather than to any deferred maintenance.

**ANNUAL RENEWAL RATES.**—Table 1 gives the annual renewal rates expressed as a percentage of the total ties in group, for groups having average lives from 7 to 30 years. These rates when applied to each group of ties separately will give the number of ties to be removed each year from the time the group was inserted until the last ties are removed. This table is based on a set of renewal curves developed for the purpose of predicting renewals. There is an individual curve for each average life. To show the

### Thousands of Ties

FIG. 3.—Illustration of predicted renewals after 1932 on a road having 1,241,149 ties in track. This figure also shows what effect on renewals would be, were a change made from 23-year ties to 8-year ties in 1938.

relation between the percentage of ties removed and the percentage of average life, the cumulative renewal curves for average lives of 8, 12, 16, 20, and 24 years are plotted in Fig. 5. These curves, in cumulative form, are based on the theory that the longer the average life the more nearly vertical will be the central part of the curve expressing the relation between the percentage of ties removed and the percentage of average life. This theory is supported by data now available for ties producing average lives up to about 18 years and it is assumed that it will hold true with the longer life ties.

FIG. 4.—Illustration of predicted tie renewals on two roads having the same number of ties in track, Road B having started the use of the longer-life ties several years prior to Road A. This illustrates the fallacy of drawing conclusions from a comparison of tie renewals per mile, one road with another, without first ascertaining the normal renewal requirements of each road.

FIG. 5.—Comparison of selected renewal curves from Table 1, plotted in cumulative form.

## PROCEDURE FOR MAKING PREDICTION BY USE OF TABLE 1

## Data Required

- (1) Year for which prediction is desired.
- (2) The average life of each class of ties in track and the average life of the ties to be used in the future. (A method of determining the approximate average life of ties in track has been explained in another section of this report.)
- (3) The number of ties of each class inserted annually in replacements and new work, prior to year for which prediction is made. Where track is old, the calculation must start far enough back of the first year of predicted renewals to make certain that all ties previously inserted which become due for renewal during the first year of predicted renewals will be included in the summation of renewals for that year. For example, if it is desired to start prediction with the year 1932, it is first necessary to determine what ties previously inserted will be renewed during that year. If the shortest average life of ties used was 7-years, by referring to Table 1, it will be found the last ties of the 7-year groups will be due for renewal during the 12th year after they were inserted. As far as the 7-year ties are concerned the calculation of the prediction starts with the ties inserted in 1920, and if there were no ties inserted prior to that time with an average life longer than 7 years, 1920 becomes the first year in the calculations of the complete prediction. The renewal rates as taken from Table 1 are applied to all groups of one class inserted prior to the first year of prediction.

Table 2 illustrates a form for tabulating the results obtained from the above calculations.

By the use of renewal rates in Table 1, applied to 143,811 ties with an average life of 7 years inserted in 1931 (as shown in Table 2), the predicted renewals of these ties would be as follows:

| (1)<br>Year | (2)<br>Years of Service | (3)<br>Per cent of total inserted to be removed each year | (4)<br>Number of ties to be removed each year |
|-------------|-------------------------|-----------------------------------------------------------|-----------------------------------------------|
| 1931        | 0                       | —                                                         | 0                                             |

| Total       |                         | 100.0                                                     | 143811                                        |

The figures in Column (3) were taken from Table 1 and represent the per cent of the 143,811 ties inserted during 1931 that are to be renewed during each year as shown in Column 1. The number of ties to be renewed each year as shown in Column 4 are then tabulated on a form similar to the one shown in Table 2. A separate tabulation must be made for each class of ties, and the summary of the tabulations by years will be the completed renewal prediction.

The graphic form of presenting the predictions as used in Fig. 1, 2, 3 and 4 is not necessary but it shows clearly the fluctuations in the renewals and can be used readily for making comparisons.

### METHOD OF DETERMINING APPROXIMATE AVERAGE LIFE OF TIES IN TRACK BY USE OF TABLE 3

Table 3, showing the percentage of ties remaining in track at the end of each year during the life spans of groups of ties producing average lives from 7 to 30 years, was calculated from the annual renewal rates shown in Fig. 1.

When records are not available to show what ties have been removed in making renewals in the past, it is not possible to compute the exact average life produced by each of the different classes of ties, but where data are available as to the number of each class of ties inserted each year, and the number of each class of ties in the track at the end of some year, the average life of each class can be estimated by a cut-and-try method, using Table 3.

In the early years of the life spans of ties the renewals are light and will probably vary considerably from the renewal curves shown in Table 1, until 10 per cent or more have been removed from the track. For this reason, the use of Table 3 should be limited to those groups in which 10 per cent or more of the ties inserted have been removed from the track.

The cut-and-try method of determining the estimated average life of ties in track when the only information available is the number inserted each year and the number remaining at the end of some year can best be explained by an example. On a road where there were 7,749,863 ties in track at the end of 1931, it was estimated that 43 per cent or 3,332,441 were zinc treated. Zinc treated ties had been used on this road during the years 1915 to 1928 inclusive, and the number inserted each year is shown in Column 2, Table 4. It was assumed that these ties produced an average life of 14 years, and on this basis the calculation shown in Table 4 was made to determine how many ties would remain in track at the end of 1931. The year 1931 would be the 16th year of service for ties inserted in 1915, and from Table 3, it is found that at the end of the 16th year 16.3 per cent of the 14-year ties remain in service. In the same manner the per cent remaining at the end of 1931 was taken from Table 3 and listed in Column 3 of Table 4, for all ties of this class inserted. It was found from Table 4, that the 14-year average life would have left a total of 3,590,654 ties in track at the end of 1931, and, therefore, the assumed average life was too long. Using an average life of 12 years 3,022,449 ties would have remained in track at the end of 1931, and with an average life of 13 years there would have been 3,341,907 ties in track. The latter figure is close to the number estimated to be in the track at the end of 1931, and the average life of 13 years was therefore used for making the renewal prediction. This same method was used for determining the average life of the untreated ties on this road, but as the use of creosoted ties was a fairly new practice only a small number had been removed at the end of 1931 so that it was necessary to estimate the average life of this class of ties on the basis of experience of other roads.

If records have been kept on test sections of track, the average life of the ties can be estimated for use in making renewal prediction of all ties of that class. Unless there are a large number of ties in the test sections, the cut-and-try method of determining the average life should be used as it takes into consideration all of the ties in track. The use of Table 3 for estimating the average life of ties in a test section, when 10 per cent or more have been removed, is explained in the following example. If in a group of ties 22 per cent have been removed at the end of 7 years of service, leaving 78 per cent in the track, it is found that in the line for 7-years service in Table 3, the figure 77.3 in the column headed 9-year average life is closest to the actual figure. The average life can therefore be assumed as 9 years.

| 1933                          | ..141254      |                                                |       | 0     |       |       |       |       |       |       |      |      |      |  |
| 1934                          | ..141608      |                                                |       |       |       |       |       |       |       |       |      |      |      |  |

A prediction of renewals of 7-year ties was used to illustrate the form of tabulation shown above. The number of ties to be renewed each year was found by applying the renewal rates for 7-year ties to the number of ties inserted as shown in the second column. The actual renewal figures were used in the second column for the years 1919 to 1931 inclusive. The total of renewals in column headed 1932, is the prediction of renewals for that year. The predicted renewals for 1932 is placed in second column and the renewal rates applied to this figure in the same manner as for the previous renewals in this column. This process is continued for the years subsequent to 1932 if the prediction is to cover more than one year. The prediction is completed in the above tabulation for the years 1932, 1933 and 1934.

TABLE 4.—Calculation made by use of Table 3, to determine the number of ties remaining in track at the end of 1931, using an average life of 14 years.

| (1)             | (2)             | (3)                      | (4)                  |
|-----------------|-----------------|--------------------------|----------------------|
| <i>Year</i>     | <i>Number</i>   | <i>Per cent in Track</i> | <i>Ties in Track</i> |

## Appendix G

(9) TYPE OF TIE PLATE BEST ADAPTED FOR USE WITH  
PRE-ADZED TIES

H. R. Clarke, Chairman, Sub-Committee; W. C. Bolin, R. E. Butler, Doyle Campbell, E. E. Chapman, L. O. Lower, L. T. Nuckols, L. J. Riegler, L. L. Tallyn, W. W. Wysor.

Since tie plates are placed on pre-adzed ties for the same purpose as on all other ties, that is, to prevent or reduce mechanical wear of ties and to strengthen the track structure, the same dimensions and data for designing tie plates should be followed in both cases (page 251, 1929 Manual). The only difference that might be justified is in the construction of the bottom of the plate.

Dr. A. N. Talbot, in report on "The desirability of reducing to a minimum the present variability factor in track" (Bulletin 346), has shown great variation in the stresses in the base of rail as measured at every other tie and has indicated the extent to which unequal tie support contributes to this.

Fairly comprehensive laboratory tests have indicated that a load considerably in excess of the usual wheel load is required to completely seat even a flat bottom two-rib plate in hardwood ties and a much greater load is required to seat plates having a more intricate bottom design. Rather extensive field observation has shown that in the case of plates with under side of various designs other than the flat bottom, two or three years' service is required to completely seat such plates. This condition results in looseness developing between the tie and the rail, as seating of the plate progresses. This condition was found by Dr. Talbot and tends to increase "the variability factor in track".

The plate bearing surfaces on pre-adzed ties are more uniform and more nearly in the same plane than if ties are not adzed. Therefore there is little need to provide for uneven initial bearing of the tie plate. It is desirable to use a plate which will be fully and completely seated as quickly as possible in order that the tie may be solidly tamped to a uniform and equal bearing. A flat bottom plate meets this requirement.

The Committee recommends a plate of adequate size and proper design to afford maximum protection from mechanical wear. If the plate is fastened to the tie independently of the rail fastening, the bottom should be flat and smooth. If the plate is not fastened to the tie independently of the rail fastening, the bottom should be flat with two shallow ribs at right angles to the length of the tie. These ribs are to increase resistance to lateral thrust and to assist in maintaining gage.

If plates with ribs are used, the Committee recommends the grooving for these ribs in connection with pre-adzing. This permits immediate seating of the plate and prevents cutting and breaking of the wood fibers after treatment. In order that pre-grooving may not complicate tie supply, the grooves should conform to a single standard location which shall be the same on all ties, the necessary accommodations for different rail sections to be made in the locations of the ribs on the bottoms of the tie plates. This recommendation is made with a knowledge of the facts that tie plates must be designed for given rail sections and must therefore be changed when rails of different section are laid and that properly protected creosoted ties will usually outlast one or even several changes of rail unless the ties are prematurely destroyed as the result of adzing or spiking at the times when rail is relaid. The single standard location for pre-cut grooves will materially lessen the necessity for adzing at the times when rail is relaid.

## Appendix H

**(10) ECONOMY OF USE OF TIE PLATES WHICH ARE SECURED TO THE TIE INDEPENDENTLY OF THE RAIL FASTENINGS, WITH PARTICULAR REFERENCE TO THE EFFECT ON TIE LIFE**

W. C. Bolin, Chairman, Sub-Committee; R. E. Butler, Doyle Campbell, E. E. Chapman, H. R. Clarke, R. M. Jolley, L. O. Lower, L. T. Nuckols, L. J. Riegler, L. L. Tallyn, W. W. Wysor.

A comprehensive questionnaire was prepared and submitted to the railroads. Forty responded and of these twelve were able to report on the subject from actual experience. The response received indicated that this subject has been given serious consideration and a number of railroads have made quite heavy installations.

Independently fastened tie plates may be divided into two classes:

(a) Plates fastened to the tie independently of and in addition to the spikes which hold the rail down.

(b) Plates fastened to the tie independently of the rail fastening and with no spike bearing against the rail, the rail being fastened to the plate rather than to the tie.

Examples of both classes are usually larger than ordinary plates. Those of class (a) may have either single or double shoulders. Those of class (b) usually have double shoulders. Spikes used with class (a) are usually cut spikes or lag screws, though in some cases screw spikes are used. Screw spikes are used exclusively with class (b).

Most roads which have tried the tie plate which is secured to the tie by independent fastenings agree that there is an increase in tie life, an increase in rail life, and a decrease in the labor required for surfacing and regaging. The time in use has not been sufficient to determine the amount of these savings.

While there is some difference of opinion as to the effect on the labor cost of making tie renewals, it appears that this cost will not be affected materially.

The labor cost for relaying rail appears to vary with conditions: (a) Where rail can be renewed without disturbing the tie plates a saving is indicated; (b) where tie plates have to be reset or renewed, an increase in cost is indicated.

The second class of plate results in stiffer track and this permits lessened expansion allowance which, in turn, reacts to give lessened rail batter. The wave motion under trains is lessened and this reduces the ballast disturbance. In some types of class (b), rail renewal, of the same rail section, can be made without damage to the tie through respiking.

There is an increase in the cost for tie plates that are independently fastened. It has not been determined whether the saving resulting from increased rail and tie life and decreased maintenance labor is sufficient to warrant this expenditure.

Many roads report that the mechanical wear of the tie resulting from the cutting and abrasion effect of plates and tearing and splitting effect of spikes has been materially reduced, permitting the full benefit of the expense of tie treatment. However, the tie plates used with independent fastenings are larger and heavier than those used on the same class of track where independent fastenings are not used. We have not been able to determine to what extent this increase in size and weight, regardless of method of fastening, has had on the elimination of mechanical wear of ties.

The use of independently fastened plates has not been of sufficient extent or duration to permit conclusions as to the amount of the increase in tie life, although increased tie life is indicated.

## Appendix I

(11) METHODS OF INSPECTION FOR RENEWAL OF TIES,  
CHECKING THEREOF AND ADHERENCE THERETO

R. S. Belcher, Chairman, Sub-Committee; H. F. Brown, S. B. Clement, R. L. Cook, E. L. Crugar, H. R. Duncan, C. F. Ford, C. W. Greene, R. M. Jolley, J. E. King, C. S. Kirkpatrick, F. C. Krell, S. E. Shoup, L. L. Tallyn, J. W. Tate, R. C. Young.

In order to develop information on this subject, your Committee last year sent out a questionnaire to members of the Association in an attempt to ascertain not only present practice of the several railroads, but also the opinion of those answering the questionnaire concerning present practice together with suggested changes and improvements. Replies were received from sixty-one roads having an aggregate mileage of approximately two hundred forty thousand miles. The Committee is very grateful for the hearty response to the questionnaire and the complete information and discussion given by those answering. The questionnaire appears on page 351 of Vol. 34 of the Proceedings.

**Field Inspection to Determine Renewals Necessary**

All roads reporting consider field inspection necessary as a basis for estimating the tie requirements for the following year. In general, this inspection is made in the fall of the year, but one road reporting not only makes this Fall inspection to determine the number of ties needing renewal during the following calendar year, but in addition, each month a portion of the territory is covered for the purpose of indicating to the section foreman those ties which will be renewed by him during each month.

On twenty-one of the roads reporting, this inspection is made by section foreman and roadmaster\* together; on eighteen, by section foreman checked by roadmaster\*; on eleven by roadmaster\* only; six report that the section foreman makes the inspection alone, one reports that the section foreman makes the inspection supervised by an engineer, and one that the inspection is made by a special inspector.

On one road where the inspection is made by the section foreman and checked by the supervisor, a further inspection is made by the roadmaster of those locations where renewals appear unusual. On another road where inspection is made by the section foreman and roadmaster and checked by the Division Engineer, a further check is made by a maintenance inspector from the office of the Chief Engineer, sufficient to insure a conservative inspection. On another road both supervisor and assistant supervisor inspect with the section foreman, and on another road where inspection is made by the section foreman, a check is made by the roadmaster and Engineer of Maintenance of Way. On several roads where both section foreman and roadmaster make the inspection of important main track, inspection of back tracks and some of the branch lines is made by the section foreman alone, and only a general inspection and check of such tracks is made by the roadmaster.

It is evident from the information received that a great deal of importance is attached to this inspection of ties in track upon which the following year's tie renewals are based, and while there is considerable variation in the method used, yet practically all roads make some kind of a check of the original inspection. A few of the roads are of the opinion that something more than even the most careful inspection and check of same is well worth the time and effort required. One of these states that their present methods are the result of more than two years' field work by their general maintenance inspector who has conducted numerous meetings with their maintenance forces on the subject of economy of maintenance in its various phases and particularly in the use of

\* Or Track Supervisor.

cross and switch ties for the proper maintenance of the railway, taking into consideration the class and density of traffic on the various lines. After these meetings, which are attended by the section foremen, track inspectors, roadmasters, Division Engineers and Engineers Maintenance of Way, it has been the practice to make a check of tie conditions on a convenient mile of track. After those in attendance have walked over this mile, all present make an estimate of ties requiring renewal in this mile. After comparing results, they return over the same mile, testing the condition of any of the ties which have been included in the estimate of those present, deciding whether or not they should be removed. The object of this is to impress on the foremen the necessity of making their decision on each questionable tie as it is at the time of inspection rather than as it may be six or eight months later. It has been found by this road that inflated estimates are generally the result of attempting to estimate the condition of the ties as they will be some months later.

After the meetings referred to, it is the practice to check at least one mile of each track section, on each division by a group of five to six foremen, track inspector, roadmaster, and Division Engineer, and compare results with the original estimate. In all cases, the group agrees as to the actual requirements. The present plan of this road, of having section foremen prepare the original estimate, developed from a former plan of checking one or more miles on each section and applying the percentage of increase or decrease to the original estimate for the remainder of the section. This road believes they are now getting away from an arbitrary method of adjusting estimates. They feel that while all of this has taken a vast amount of time, yet thus far the results have more than justified the effort, because they are obtaining a more uniform and satisfactory distribution of renewals than formerly. They expect to continue the present system of checking tie conditions, and are of the opinion that their maintenance forces are very much more "Tie minded" than ever before.

As another illustration of the importance attached to the inspection of ties in track as a basis for renewals, another road concisely states their views on this subject as follows:

"The practice as outlined is that now in effect and is the method we have been following for the past several years. It is the result of a good deal of argument and discussion among ourselves and we think is the practice best adapted to secure the economical use of ties and at the same time keep the track tied up to the standard desired. Summed up, it is our opinion decision as to ties that are to be renewed should be made by the section foreman with very close and constant supervision by the roadmaster and continual checking by all other officers concerned with maintenance of way, as indicated, up to and including the Vice-President. Our experience has convinced us that it is not possible to make an inspection of ties in the fall which will correctly indicate those which should be renewed the following spring and summer, yet the inspection in the fall must be made as a basis of the tie allotment and for use in unloading and distributing ties as they are shipped out. Another advantage of this inspection is that it gives the roadmaster and the section foreman a very accurate idea of their track conditions, especially in regard to ties, just before they go into the winter.

"It is our belief that the tie allotment authorized should be held if possible somewhat below what we may think the real requirements will be, as we know that if the allotment is liberal and ties furnished accordingly, they will be used in the same way. Therefore, it is our practice to authorize an allotment which we think will be a little below the actual requirements and then increase this allotment as the working season progresses the following year as may be necessary, planning of course, to have the necessary ties in stock to enable these increases to be taken care of when authorized.

"It is our opinion the final inspection to determine renewals should be made as the work is being done, this inspection being made by the section foreman and if at all possible by the roadmaster or the track supervisor working with him. Where we have track supervisors, we require that they, with the section foreman, inspect all main track ties to be renewed before taken out. Where we do not have track supervisors, we expect the roadmaster to do this just as much as he can and hold him responsible for all ties taken out."

### Marking Ties for Renewal

Seventeen of the sixty-one roads reporting do not mark the ties which are to be renewed. Of the remainder, sixteen chip off a corner or notch tie with axe or adze, nine of the roads spot the ties to be renewed with paint, eight place a spot of paint on web or base of rail directly over the tie to be renewed. White, yellow and red are the colors used and the practice of one road is to alternate each year between yellow and white. Two roads mark the ties to be renewed with crayon and six mark the rail with crayon or keel directly above the tie. Three roads mark the ties to be taken out with a branding hammer. One of these roads on first inspection brands the ties with a circle about one-inch in diameter on the top surface, line end, and on the second inspection, the ties are branded with a circle about one and one-half inches in diameter with the letter "R" inside that circle, which mark instructs the foreman to renew the tie. One road uses a vertical keel mark on the web of rail over the tie to be renewed. If reinspection of roadmaster and Engineer shows that the tie can be retained in service for another year, a cross line parallel with the rail is made through vertical keel mark of the section foreman, making the character "plus". One of the roads not now marking ties for renewal believes it is good practice to do so and hopes to start the system of marking next year.

### Reporting Ties to be Renewed

Of the seventeen railroads which do not mark the ties to be removed at the time of inspection, one compiles results of inspection by mileposts and telegraph poles, nine by miles, and six by sections. One railroad reports the ties by five hundred-foot sections of main track, and yard tracks and sidings are reported as individual tracks. In general, whatever the unit used for reporting the number of ties needing renewal, this unit is separated as to tracks.

Railroads marking ties for renewal in general make as detailed an estimate as those that do not mark the ties to be renewed. Of the forty-four roads which mark the ties for replacement, two compile results by miles and telegraph poles, twenty-nine by miles, nine by sections and one by station stakes or mileposts. Three of the roads reporting ties for renewal by miles in main track report each side track as a unit. One road uses quarter-miles for main tracks and individual sidetracks and yard tracks; one road uses a unit of each five telegraph poles of each mile. In most cases, ties for renewals reported by telegraph poles, mileposts, quarter miles etc. are compiled to section, district and division totals.

### Check of Original Field Inspection

The majority of roads reporting make a careful check of the original field inspection, although the methods used vary considerably. Twenty-eight of the roads report that the check is made by roadmasters, supervisors, or assistant supervisors and on twelve roads the Division Engineer makes the check. On one road the check is made by Division Engineer and a representative from the office of Chief Engineer Maintenance of Way; on another by the general roadmaster, on another by the general supervisor maintenance of way, on another by the superintendent maintenance of way and roadmaster; on two roads by the District Engineer Maintenance of Way, on another by the Division Engineer and general roadmaster; on two roads by the Division Engineer and roadmaster; and on one by the general track inspector, tie and timber agent and assistant engineer maintenance of way.

On one road the original inspection is made in the fall by the section foreman and roadmaster, and is check-inspected just before renewals in the spring by the same parties.

Two roads have special maintenance inspectors and the check of the original field inspection is made by inspecting ties at random on various sections, where renewals seem to be out of line. On one road special track inspectors are assigned to a part of the territory. On such territory, a detailed check is made of the foreman's estimate by the track inspector. After this has been completed, the roadmaster, accompanied by track inspector and section foreman, makes a recheck of such portions of the foreman's territory as may be necessary to satisfy himself that the count is correct. The Division Engineer is also required to make such check of estimates as may be necessary to enable him to assume full responsibility for them.

On one of the roads where the check is made by the District Engineer Maintenance of Way, such check is made only at points where recommendations for renewals seem excessive, but the record of field check as made by roadmaster and foreman is carefully checked in detail. The District Engineers are on the line practically all of the time and have a definite and accurate idea of tie conditions on their districts.

Likewise, on another road on which check of the original field inspection is made by the Division Engineer, sufficient territory is covered on each supervisor's district to enable the Division Engineer to know that the inspection for the whole division is made in a uniform manner.

Check of the original field inspection on another road is made by certain special maintenance inspectors, reporting to the office of Chief Engineer of Maintenance. These inspectors have previously made careful study of the renewals per mile over a period of years approximately equal to the average life of the ties to be renewed. The inspectors' observations of the records of the current inspection have indicated those locations where apparent irregularities in proposed renewals are evident. Insofar as the number of inspectors permit, they make reinspection of such miles. In addition, the reinspection of such locations is supplemented by requests to have the track supervisors reinspect those particular miles.

It is the practice on one road, on which roadmaster makes a check of the original inspection, that the roadmaster make a sufficient field check to satisfy himself so that he can assume the responsibility for the final recommendation on each mile of his section. On some sections it is necessary for the roadmaster to personally inspect every tie of the section foreman's recommendation; on others, the checking of a short distance is usually sufficient. Where roadmaster disagrees with section foreman's recommendation, he uses his own mark which is a vertical crayon mark on the rail above the tie in question so that if section foreman has put a horizontal mark on the rail, indicating that the tie is to come out and the roadmaster figures it should remain in track, he converts section foreman's horizontal mark into a cross by the use of his vertical mark.

Until about two years ago it was the practice on one of the railroads to not only have the original inspection of section foreman reviewed by track supervisor and afterwards by roadmaster or Division Engineer, but also to have an individual check made of part of each division by a visiting roadmaster, who would select from his list certain miles which seemed to require checking and make his report on those miles. In another case, where the original inspection is checked by Division Engineer, a general check of all divisions is made as the work progresses by the Engineer of Track and sufficiently by the Engineer Maintenance of Way to satisfy himself that the spotting is proper.

On one of the roads where the section foreman's field inspection is checked by the roadmaster and an Engineer for ordinary renewals, in cases where renewals are being made by ballasting or surfacing gangs, an inspector is usually kept with the gang constantly to mark the ties to be removed or to change the marking if this is shown to be necessary after the track is raised or ballast removed.

On one railroad where preliminary inspection is made during the early part of December by the roadmaster, the ties to be renewed are not actually blazed until a second inspection is made by the roadmaster which is usually made in January or February, at which time the roadmaster himself blazes the ties to be renewed. The preliminary inspection made in December is to enable a fairly accurate estimate of requirements for the ensuing year and it is generally found that the two estimates made by the roadmaster are not very far apart, and, as a general proposition, the number of ties actually blazed totals somewhat less than the estimated number.

While there is considerable diversity of methods used by the various roads as a check on the original inspection, it is quite evident from the study of replies to the questionnaire that the check of original inspection is considered of much importance, and while all roads do not reinspect all ties, a sufficient reinspection is made by some competent official to assure the accuracy of the original inspection.

### **Variation between Original Survey and the Check**

The majority of those reporting have found that the number of ties estimated ready for replacement at the time of the original survey is greater than the total requiring renewal shown by the check. This difference is variously reported at five to twenty-five per cent. One road reports that some section foremen vary as much as forty per cent while others make very close estimates. Some roads report little variation between the original survey and the check. One states that usually the section foremen and roadmasters report a fewer number of renewals to be necessary than the Division Engineer finds to be the case. A few roads find there is considerable variation in both directions. The general experience seems to have been that as a rule the original survey made by foremen and roadmasters can be somewhat reduced but that this is not always the case and occasionally an increase is found to be necessary as a result of the second check.

One Chief Engineer points out that there is a tendency on the part of the section foreman to overstate his requirements in anticipation of an allotment which is less than that for which he is asking. Another Engineer notes that the tendency shown by the rechecks is to indicate decreases in requirements which of course show great variety and extremes per mile in individual cases. The majority of such rechecks, however, probably fall near the average decreases thus found as a result of the work on the system which, for the last year tabulated, indicated fifteen per cent. When the rechecks were first started on this road, it was found that for the system as a whole, the inspection developed a total for the system of renewals required thirty per cent in excess of the actual renewals made during that year. Five years later with the system of rechecking in effect, the per cent of inspection over actual renewals had been reduced to nine per cent. The method simply resulted in causing the original inspectors, the supervisors, gradually to more nearly exercise the same care and attention that was given by those who made the reinspection.

Another Chief Engineer calls attention to the fact that the check on his railroad indicates that now the sections are accurately marked for renewal at the time of the original survey, but this is due to the fact that this road has been spotting ties for nineteen years. Considerable educational work was required in the first years the present method was in effect. Another report states that section foremen are more careful and consistent in their first inspection because of knowing that a check would be made by the Supervisor.

### **Inconsistencies in Estimates for Different Territories Under Similar Condition of Tie Timber, Track and Traffic**

The personal equation is the reason given most frequently for inconsistencies in tie renewal requirements as reported by section foreman, roadmaster, etc., for different terri-

tories under similar conditions of tie timber, track and traffic. Such inconsistencies as occur are in general explained by normal differences in judgment as to what is considered the proper standard of renewal under any set of circumstances, is the opinion given in one reply to this question, while another states the only inconsistencies found are such as would be expected to be found upon a study of human nature. These inconsistencies always exist but with constant attention by maintenance officers improvement may be made.

One maintenance official calls attention to the fact that the section foreman and roadmaster frequently call for fewer renewals on pieces of track which have been reballasted in recent years than are necessary to keep up current maintenance. This is believed to be partly due to reluctance to open up the new ballast any more than necessary. A very considerable number of the roads report that variations due to the personal equation are corrected to a large extent by the use of uniform instructions and by holding staff meetings, and by a long and continued process of education. Many inconsistencies or variations appear in the original survey which are adjusted in the following recheck. One road notes there is more variation apparent when ties of short life are being used than is the case where ties are either treated or are of a long life variety.

A portion of the roads report few inconsistencies in recommendations for renewals. A reason given for the uniform reporting is that methods and standards have been in effect for so long a time that officers and men are familiar with and capable of carrying out such methods with a fair degree of uniformity.

#### **Methods Followed for Tie Allotments When Supply is Inadequate to Cover Amount Determined by Field Inspection**

On some roads a sufficient supply of ties is kept on hand so that it is always possible to take care of requirements as determined by field inspection and check. From a road on which this is the condition comes the following reply:

"Ties are purchased on the basis of past requirements usually well over a year ahead of the time needed. For some years past at least, our stock of ties has been large enough to permit increasing the allotment, if, as the work progressed, this was found necessary. It is our policy to keep track in good safe condition for ties. If, as tie renewals progress, the allotment is found insufficient, an inspection is made by District Engineer Maintenance of Way, accompanied by the Division Superintendent and roadmaster. Additional ties are authorized on the recommendation of the District Engineer Maintenance of Way."

Another road reports that preference is given to appropriations for tie renewals and normal replacements are made each year. When necessary to reduce the maintenance budget sacrifice is made elsewhere and they are not, therefore, confronted with the problem of adjusting the tie allotments to curtailments in the authorized supply. Others secure authority for the purchase of additional ties.

The larger portion of the roads report some method for the allotment of the tie supply when this is less than the amount determined by field inspection and check. Various methods in effect on these roads are: Ties are used where most needed with a view to making safe operating conditions.

Important main lines are given preference. Minor tracks are assigned enough ties to make them safe for the service required.

Track being surfaced and curves are usually favored.

Preference is given to tracks carrying the heaviest tonnage.

In some cases where there is no great difference between the ties available and the number needed, the allotment is prorated.

On some roads allotments are made on the basis of reinspection.

As one Chief Engineer points out, this condition of insufficient tie supply usually comes in times of reduced traffic when a considerable number of yard tracks are not required and can be spiked or used as storage tracks, on which renewals will then not be necessary.

On many of the roads, it is the responsibility of the Division Engineer or other maintenance officer to adhere to the allotment and confine renewals to locations where most needed, curtailing replacements on the basis of his actual knowledge of the traffic, speed and condition of track in his territory, all of which is given consideration in making distribution of the ties. One road uses the following definite method:

1. Allot sufficient main track ties to main line districts where traffic is greatest, to make it safe for one year.
2. Install about fifty per cent of the siding ties originally allotted.
3. Remainder of the total authorization of ties installed in main track, branch lines and main line districts where traffic is light."

One engineer states that "foremen are instructed to renew only broken ties or ties which are not holding the gage and which must be immediately renewed to keep the track safe. Data as to requirements is predicated upon check made by Roadmaster under the above rules."

On one road it is the practice to keep a careful record of locations where tie renewals have to be deferred or reduced on account of insufficient supply so that these may be given preference with the next allotment.

One Chief Engineer reports a horizontal and uniform reduction as follows:

"Tie allotments are based jointly upon a field inspection and the forecast of renewals for particular divisions, which latter are founded upon the report of tie service over a period of years past extending well beyond the average life of the ties to be renewed.

"To the extent that it is necessary to reduce allotments to meet authorities less than those indicated by the requirements as determined by the above method, it is done by horizontal and uniform reduction, with such modification as the particular immediate requirement in any locality may warrant."

Other roads report that unless there are conditions which require special consideration, the allotments are reduced proportionally. In some cases proration is applied to small units such as between telegraph poles, so that no locality will suffer unduly.

Detailed records of tie renewals have been found of value to show the relative urgency of renewals in different localities, supervisors' districts, etc. One Engineer states:

"Our detailed records of tie renewals during the past ten or twelve years, together with personal inspections of such locations where there may be any doubt as to the feasibility of making reductions, have enabled us to handle satisfactorily problems of supply curtailment."

Another states:

"Record is kept of the total number of ties in track and the number of actual renewals for years past by Supervisors' Districts. Past renewals are compared with the normal renewals on the basis of expected life and consideration is further given to the fact as to whether there are any stretches of road where the ties are beginning or ending a cycle of renewals".

Still another uses renewal records as follows:

"Usually the average renewals for the past five year period are compared with the theoretical renewals necessary to comply with our computed tie life and the limited supply is used as far as to maintain the average renewals indicated as necessary on this basis, but modified, based on judgment, to meet the obvious needs as shown by the inspection."

### Importance of Inspection of Old Ties Taken out of Track

The importance attached to the inspection of old ties taken out of track as a check on extravagance in making tie renewals is indicated by the fact that all but one of the railroads answering the questionnaire make at least an inspection of a representative number of the ties taken out of track and many have inspection of all old ties made before they are removed from the right-of-way or destroyed. This inspection is made by Track Supervisors, Roadmaster, General Roadmaster, Division Engineers, or special inspectors, and in most cases other officers check such inspection from time to time. One Maintenance Officer reports that old ties are always inspected by the Roadmaster before they are destroyed and are frequently inspected by other officers up to and including the Vice President, and an Engineer Maintenance of Way reports:

"Our instructions call for all old ties taken out to be held on right-of-way for inspection by roadmaster before being burned or otherwise disposed of. General and division officers on inspection trips make it a point to examine all old ties and carry on educational campaign among Roadmasters and Foremen to avoid removal of ties before they have served their full life. We consider this of great importance and while complete uniformity of treatment by all foremen is not obtainable, more can be done to approach this ideal by examining with the foremen ties taken out of the track, than in any other way."

Another Engineer Maintenance of Way is also convinced of the importance of such inspection. He writes:

"Frequent inspection of track and old ties taken out of track is constantly followed up by officers concerned during the period tie renewals are being made, in order to avoid extravagant or inadequate renewals. This is the most important feature controlling the expense of tie renewals that there is. Nearly all foremen, including many of the best of them, having opened up the track to take out one or more ties in a place which obviously should be changed out are very likely to take out one or more adjacent ties which are still good for one or more years if left in the track, because they feel that, having already opened up the track, it would be a waste of money not to do so, or possibly because they do not like to fill in the crib and cover up a tie which is not in good condition even though it may be good for one or two years more life if undisturbed. It is this tendency of foremen which uses up a great many ties of their limited supply on one portion of their section, which then leaves them with fewer ties than are actually needed on the balance of their section. This, of course is good argument for the marking of ties by the inspector. The trouble there, however, is that the inspectors' judgment is not infallible, nor under the ordinary procedure can he make an adequate inspection of all ties in the track in order that there will be no error in the marking of all ties he reports as necessary for renewal. It is for this reason that we do not feel the practice of marking ties by the inspector is the best method to follow. It is felt, however, that mile for mile his judgment is sufficiently good so that the number of ties he reports as necessary for renewal will average up to about what is actually found necessary when the renewals are in progress."

A Chief Engineer writes:

"Ties taken out of track are piled on the right of way, and are inspected by the Assistant Superintendent and roadmaster before being burned or destroyed, in order to prevent extravagance in the use of new ties. In case any ties are found to have been removed from track, which do not show Roadmaster's blazing, the Section Foreman is required to explain in detail why the tie was removed contrary to instructions, and if satisfactory explanation cannot be given, the Section Foreman is severely disciplined."

Coincident with the inspection of old ties taken out of track, observations are made of the track by most of the roads to know that satisfactory conditions have been provided by the renewals made.

Several of the replies to the questionnaire call attention to the fact that greater care is used in the selection of ties for renewal because it is known that there will be an

inspection of the ties removed before they are destroyed or taken from the right-of-way. One Chief Engineer states:

"Section foremen are instructed not to dispose of old ties removed from track until they are inspected by the supervisor. The Division Engineer also makes regular inspections of ties removed, and the Chief Engineer gets on the ground two or three times during the season. The purpose of these inspections is to verify the judgment of the supervisors in marking ties for renewal. Experience has educated the supervisor, so that very few ties are marked that should not have been taken out. The inspections by the Division Engineer and Chief Engineer have a tendency to make the supervisors more careful in marking ties for renewal."

Another Chief Engineer whose road makes it the practice to inspect ties after they are taken out of track to avoid extravagance, states however:

"It is my experience that the tie allowance is the governing factor. The only way to avoid taking out good ties is to limit the allowance to absolute necessities and our entire tie allowance program is carried out on this theory."

The one road reporting no inspection of old ties is made, states that it has been the practice in the past to inspect old ties taken out of track but infrequent checks and the method followed in marking ties for renewal show a general check unnecessary. On this road Section foremen and track supervisor make independent field inspections and are checked by Division Engineer. The ties are not marked for renewal until after the allotment is fixed and prior to the renewal of the ties, when the Supervisor, accompanied by the Section Foreman, goes over the tracks and marks with keel all ties to be removed.

#### **Latitude Allowed Section Foremen Renewing Ties at Variance with Yearly Maintenance Allotment**

On the majority of railroads section foremen are not allowed to renew ties in excess of the yearly allotment. On a great many of the roads which do not allow the section foremen to exceed the allotment, if it is found that for one reason or another more ties are needed than provided for, the situation is called to the attention of the roadmaster or track supervisor and through him arrangements made for the additional ties needed.

On one of the roads where no latitude is allowed the section foremen in removing ties at variance with the yearly maintenance allotment, that allotment is arbitrarily increased 5 per cent above the number spotted over the division to compensate for errors of judgment and occasional renewals caused by derailments and other damage. Another road adds 10 per cent to the main line spotting to cover conditions as they appear in the Spring. In this case the ties are spotted in September and October, while renewals do not commence until the middle of April. On one road where the renewal program is based on reports of ties needed on each mile of main track and each siding separately, the section foremen are not allowed to deviate from the number of ties assigned each mile or siding, but if, due to changed conditions, it is the opinion of foremen and Roadmaster that additional ties are required, a reinspection is made and additional ties furnished if needed.

On one road on which foremen are not allowed to exceed the allotment for their section without authority, and this allotment of ties is based on inspection made in the Fall, actual renewal of ties is determined by a more careful examination at the time the work is being done, this examination being the governing factor. Roadmaster and Track Supervisors inspect a large percent of the ties with the section foreman before actual renewal is made, this inspection being carried along throughout the renewal season, keeping ahead of the work.

On a road where it is the practice for the Track Supervisor to make the field inspection to determine the renewals necessary, the section foremen are generally given the

allotment of ties for their section for the year, which are to be distributed per mile in proportion to the ratio established by the inspection. This distribution is not a hard and fast rule, the section foremen being required only in the event of finding it necessary to extend the renewals on one or more miles, to reduce them in equal number on other miles. If necessary to increase the total renewal for the section additional authority must be secured.

In practically all cases where section foremen are allowed no latitude otherwise, they are permitted to take out broken ties, and ties made unsafe by derailments. One road reports that each section is given a monthly allotment of ties and section foreman must not exceed this allotment without permission. If additional ties are requested, track supervisor makes a personal inspection to determine actual requirements and makes necessary adjustments in tie allotments.

About one-fourth of the roads reporting rely upon the judgment of the section foreman to a greater degree than indicated above. For instance, on one road the foremen are permitted to deviate from the program if bad ties are found which were not in evidence at the time of the original inspection. On another road the foremen may remove ties other than those marked by the track supervisor if he thinks necessary, but they are left beside the track and not destroyed until the supervisor has an opportunity to inspect them. On several roads the foremen are permitted to vary from the allotment only to the extent which may be necessary to keep the track in safe condition. One road states that the judgment of the section foreman is trusted pretty freely and they rarely find him wrong. On another road the section foreman is permitted to remove any tie that will not in his judgment last one year, whether such tie has been spotted for renewal or not.

On a road on which it is not the practice for the roadmaster or supervisor to spot the ties for renewal, the section foremen are permitted to use their own judgment but are watched very closely to see that ties are not removed that have service life in the original location under heavy traffic. On this road many treated ties are removed from main line high-speed track due to mechanical wear that renders them unsafe for such locations. All such ties are used again in minor sidings and give many years of additional service.

Another road considers the count of ties to be removed and the allotment by sections only as a guide, and it is the endeavor to avoid applying any pressure by general instructions to get in ties simply to accomplish renewal of the program allotment. On this road it is impressed upon the roadmaster and foremen that each renewal of a tie is a separate and distinct undertaking regardless of the allotment or program. In this connection it is pointed out by many that the best time to inspect the ties is after the track is jacked up, while inspection at the time the ties are spotted is necessarily less complete and ties which look good on first inspection may show imperfections after the track is raised.

### Advantages and Disadvantages of Spotting Ties for Renewal

Marking ties for renewal is a practice having many advantages and few disadvantages is the opinion of a large majority of the engineers answering this question. That this practice is economical and educational is the opinion of most of those in favor of marking the ties which are to be renewed. At least the approximate number of ties to be renewed can be counted and their location be likewise determined beforehand. This, as stated by one engineer, permits ties to be distributed exactly in accordance with requirements, thereby saving handling and trucking. It also enables any officer who may desire to check any portion of the track in advance of renewals, to determine the extent and justification of the renewals.

When the spotting is done by the supervisor, or by the section foremen and checked by the supervisor or roadmaster, it places the responsibility on the supervisor or roadmaster instead of on the section foremen and results in more uniform practice for the entire railroad.

That a check of the actual condition of the ties, as well as the judgment of the supervisor or roadmaster, can be made by any supervisory officer on the ground, and that the moral effect of the marking of the ties for renewal is good, and more care is used by those marking the ties because it is known that a future inspection of the marked ties will be made, is the opinion of many.

In the opinion of several of the engineers reporting, marking of ties to be renewed enables a better programming of the renewals for the following year and a closer estimate of ties needed for replacements than can be made by any other method. One Chief Engineer lists the advantages of spotting ties for renewals as follows:

1. It eliminates guessing as to the condition of the ties in track and as to the number of renewals required.
2. It gives a definite record of the physical condition of the ties in the property.
3. Being the basis for the allotment, the record of required renewals per mile of track, enables definite distribution of ties to the exact location where needed and avoids cost of rehandling.
4. It provides a complete adequate record of maintenance requirements in respect to this one most expensive item of all Maintenance of Way and Structures expenditures.

About 10 per cent of the engineers reporting are of the opinion there is no advantage gained by marking ties to be renewed, and some feel the practice is an actual handicap to proper and economical maintenance. The reasons given are:

1. Ties are renewed because marked which are afterwards found serviceable for another year.
2. The additional expense of marking is not justified.
3. Marking is unnecessary because section foreman can be trusted to decide whether any given tie should come out or not.

It has been the observation of one officer that where cross ties are spotted for renewal there is a tendency to take out the tie even though a more careful examination of the tie after the track is jacked up may indicate that renewal is unnecessary. He is of the opinion that there is a tendency on the part of the section foremen to take the position that because the tie is marked, his responsibility in the matter has ended.

A Chief Engineer on whose road it is the practice to mark the ties to be renewed writes as follows:

"Most main track ties are installed in sections that are given a general raise of about 2 in. and thoroughly tamped. Many times ties that look reasonably good on top have to be renewed due to decay or other causes. The Foreman in charge should have the privilege of using good judgment in such cases, and not held down to ties that are only spotted."

One one of the roads on which it is the practice for the track supervisor to spot the ties to be renewed, carefully checked by his Division Engineer and the office of the Engineer Maintenance of Way, this practice, in the opinion of the Chief Engineer of that road, has resulted in a tie allotment which, when forwarded to the management, can be properly defended. He writes:

"On this road we started spotting ties in 1930. Our allotment for ties in 1929 was 960,000; in 1930, 731,000; in 1931, 624,000; and due to the very careful spotting and on account of financial conditions we were able to get along in 1932 with 223,000—our estimate for ties for 1933 being 495,000."

"It can be readily seen that savings due to proper spotting of ties have been considerable on this road. I feel that it would have been impossible to make this saving safely with the old method."

Another Chief Engineer is quoted as follows:

"We have spotted ties for nineteen years, sufficient to get supervisory force and section forces well acquainted with the procedure and results. When well understood and worked it should produce:

1. A good average, tie condition the entire length of each section, instead of a spotty condition.
2. Economy in renewals in that ties are not renewed which should remain and the reverse.
3. Permits the necessary planning of section work.

"I believe our organization would spot ties of their own volition as necessary to the proper accomplishment of their work."

Another Chief Engineer makes the point that spotting of ties for renewal by the track supervisor gives the supervisor a better knowledge of his tie conditions that he can obtain in any other way, and while, in addition, walking track for the spotting of ties, the Supervisor secures a more intimate knowledge of conditions on his District apart from the condition of his ties, than would otherwise be obtained.

#### SPECIAL TIE INSPECTORS

Only four of the roads use special Tie Inspectors in any way in connection with the renewal of ties. On one of these on which the original inspection is made by the Track Supervisors, Special Inspectors are used to make the check of the original inspection. When and as these Inspectors are available for the inspection of cross ties, they are accompanied on any one mile or section by the Division Engineer or Assistant Division Engineer, if available, as well as the track supervisors, and always by the section foreman. These Inspectors report to the Maintenance Engineer.

On the second road the Special Inspectors make the original inspection. Their inspection is checked by the Division Engineer, to whom they report. They are accompanied by the section foreman over their respective sections.

On the third road the roadmaster accompanied by the section foreman makes the original inspection. The District Engineer checks the roadmaster's inspection in the field on at least five representative miles of each roadmaster's territory. A statement of the number of ties needed is then prepared and sent to the Engineer Maintenance of Way. The number of ties shown on this statement is then checked in the field by a Special Inspector from the office of Engineer Maintenance of Way. From five to ten miles on each roadmaster's territory is so checked. The Special Inspector is accompanied over their respective territories by the roadmasters when making his check of their count.

On the fourth road Special Tie Inspectors are used to inspect a representative number of old ties taken out of track. A report is made of the ties inspected classifying as to causes of failure, kind of wood, kind of treatment, and ties found fit for further service in main or side track, if any. These Inspectors at times, upon request of Chief Engineer System or operating officials, inspect ties in track with a view to checking estimates of ties to be renewed in certain stretches of track where rail renewal is contemplated, or other cases where tie conditions appear unusual or ties have apparently not given the length of service expected. They are usually accompanied by roadmaster and section foreman. They report to the Manager Treating Plants and he in turn to the Chief Engineer System. Operating officials are furnished copies of reports.

Special inspectors are recruited from Assistant Division Engineers, general foremen, and engineering forces of the Maintenance Department; in general, from those employees of the railroads whose training and experience have been such that they are readily adapted to the particular class of work they are called upon to perform. One road reports that Inspectors have been trained to secure uniform and satisfactory inspection by

working jointly on identical stretches of track, or with officers to whom they report, until the standard in respect to ties to be left in track is established.

The question was asked:

"What difficulties, if any, do you find in reconciling differences in judgment as to tie renewals between Special Inspectors and section foremen who are responsible for the safety of track?"

An Engineer on whose road Special Inspectors are used states:

"There are usually differences of opinion as between Special Inspectors and section foremen as to certain of the ties marked for renewal, these ties being of the character that might be termed marginal. There have been no differences that have not been reconcilable. Usually the Special Inspector with the prestige of the knowledge of the management's policy and standard of maintenance required has been able to show the foreman every practical advantage of the acceptance of the reinspections."

The Chief Engineer of a road on which special inspectors are not used expresses the opinion that there should be no trouble in reconciling differences in judgment as to tie renewals between a competent special inspector and a competent section foreman. A tie that will not hold the rail to surface and gage should be spotted for renewal, and a tie in this condition is easily determined. The standard of maintenance determined by the speed of trains and character of traffic is one to be determined by the maintenance officers and see that it is adhered to by the section foremen.

Representatives of some of the roads not only state that special inspectors are not used on their railroad but they do not think they should be used. A Chief Engineer states:

"The roadmaster is charged with the responsibility of keeping up his track and when he goes over the division on foot, as we require him to do, he finds many things he did not know about before and corrects them. It takes as high as two months for one of our roadmasters to cover his division, but I am absolutely certain that it is the best system yet devised to secure orderly renewal of ties with the minimum outlay of money."

Another feels that it is not good practice to relieve section foreman and district roadmaster of the responsibility of marking ties for renewal. Another is of the opinion that the man on the job in charge of a particular territory is better qualified to judge the requirements because of his knowledge of actual conditions and traffic, rather than any special inspector who may be entirely unfamiliar with the conditions of a certain section or district.

Those using special tie inspectors find a number of decided advantages when special inspectors are employed as they use them. One official on whose road special inspectors are used sums up the advantages of this practice very concisely as follows:

- (a) By contacting supervisors or others who make the original tie inspections, the special tie inspectors are able to establish a more uniform character of tie inspection throughout.
- (b) Their inspection of old ties removed has similar effect in respect to uniformity of renewals.
- (c) Their association with division officers in connection with inspections and with renewals, even though but periodical, gradually leads to acceptance and application of the economic policy, which the management desires followed in connection with the use of ties.

A number of Engineers on whose roads special inspectors are not used, express the opinion that the use of special inspectors is not good practice because they cannot be familiar with local conditions and are not usually responsible for unsafe or bad riding conditions of the track. They feel that the roadmaster, or track supervisor, and the section foremen are the men responsible for track and therefore they should have the authority and be responsible for handling tie renewals.

## The Use of Statistics as an Aid to the Determination of Tie Renewals

Statistics are not used *exclusively* for the determination of tie renewals by any road answering the questionnaire, although the large majority use statistics as a check on tie renewal estimates resulting from field inspection and as a guide to the trend of future renewals. All roads report that they consider field inspection necessary as a basis for the estimation of tie requirements for the following year, but there is a great difference in the extent to which statistics are used by the several roads. In fact, a few roads make no use of tie statistics whatever so far as determination of renewals is concerned, while on other roads these play an important part in the determination of the quantity and distribution of tie requirements.

Perhaps the opinion of the greater number of those answering the questionnaire is that expressed by one Chief Engineer as follows:

"Statistics are used as a matter of comparison of tie renewals from year to year. They are a helpful guide in determining whether or not the number of ties reported for renewal is correct. They are also very helpful in determining the average length of life of the ties so that more accurate estimates can be made of future maintenance expenditures."

A considerable number of the roads have records of tie renewals for many years back and from these know what the normal renewals should be. In lean operating years when tie allotments are below normal, the Divisions adjust their renewals accordingly. If estimated requirements for any mile, section or division are much in excess of the requirements indicated by the statistics, that particular mileage is checked by most of the roads to ascertain the discrepancy. One Engineer states:

"Recommendations for allotment are checked, by subdivisions, with tie renewals over a period of years, so that the trend of renewals may be noted. This check is not a governing factor, but is used by the Engineer Maintenance of Way to keep in touch with the developments that may be occurring."

Another Engineer reports that accurate statistics are kept by his road of tie renewals by years and these statistics are used to determine the average life of the various kinds of ties. From this average life of ties and the total number of ties in track, a reasonable figure for tie renewals per year is determined. This figure is used as a check against the requests of Section Foremen and Supervisors.

A railroad on which it is the practice to have the original field inspection made by the Track Supervisors and this inspection checked by Special Inspectors, also makes extensive use of tie statistics. This road reports:

"Statistics for the determination of tie renewal requirements are tabulated for main track ties for each of the respective divisions of the System. The average life of treated main track ties and the average life of untreated main track ties is fixed by test records and by experience. The statistics for each division are carried back over a period of years extending well beyond the average life. From such a base, using a curve of rate of renewals (approximately that shown by the experience curve of the Forest Products Laboratory), it is readily possible to compute the renewals required for the current year and the succeeding years.

"The advantages of the use of statistics for such purposes are self-evident. There is nothing more certain than the average life of a group of ties having similar characteristics. Such grouping needs to be no more refined than a separation between treated and untreated ties in order to give practical and accurate results in calculation of required renewals.

"No adjustments for abnormal conditions are required in connection with the use of statistics. It first is necessary only to determine the kind of ties, treated or untreated, and the year they went into track in order to predict through the use of the adopted tie renewal curve with absolute certainty the renewal requirements for each subsequent year. With such a record available as a base, it would not matter whether the line was newly constructed or not."

Other roads have worked out curves from past renewal statistics, from which, it is reported, it is possible to forecast the approximate number of ties needed to maintain the railroad for a number of years to come. Many of the roads keep these tie records by Division, and a few by smaller units. An Engineer who uses statistics covering renewals of past years as being of value for determining system requirements and percentages of the System allowance for distribution as between division, states:

"In determination of distribution on the Division, actual facts and knowledge of conditions are of first importance. If statistics were maintained in such a way as to give a record of renewals for each mile of main track and separately for each siding, over a period of years, analysis of same might point to apparent inconsistencies which would justify special investigation, but ordinarily statistics are not maintained in sufficient detail to be of value for such purposes."

An Engineer on whose road statistics are used in the determination of total tie renewals required on System Lines writes:

"The average life for each class of tie has been determined by study of application in renewals extending over thirty years and is used in conjunction with the tie curve of the Forest Products Laboratory to project future requirements. Statistics of tie renewals on each roadmaster's district are further used as a check on apportionment between districts."

During the transition period on a railroad changing from untreated to treated ties, the use of statistics is more difficult. An Engineer on whose road the use of treated ties was begun in 1921, gradually increasing the number used annually until about 1926, when the use of untreated ties was discontinued, writes:

"At this writing we have approximately 70 per cent of all ties in service treated and, consequently, the use of statistics for determining renewals cannot be accurately relied upon, but we anticipate that when our tracks have been entirely renewed with treated ties, we will be able to rely to some extent upon statistics for determining, approximately, at least, our future tie renewals. We are of course keeping an accurate record of removal of treated cross-ties for the different causes."

In short, to quote the opinion of one Engineer, which is typical of the opinion of a very considerable number, statistics do furnish a very reliable check, but statistics alone would not suffice because they make no allowance for local conditions nor variation in quality or life of ties, or the human equation.

Conditions which affect tie renewals and which place statistics at a disadvantage for the forecasting or check of renewals, are listed by one Engineer as follows:

- (a) That at some time a large mileage might be retied with inferior wood which would come out much earlier than statistics would indicate.
- (b) Occasionally many miles of new track or siding may be added in one year and eventually more ties will be needed for such divisions than statistics will show.
- (c) The tonnage or speed of trains may be changed on a division and this would require a greater, or less number of ties per mile than statistics would indicate.

However, a number of the roads adjust statistics for abnormal conditions especially with reference to newly constructed lines. A Chief Engineer writes:

"We have developed statistical data showing the proportion of ties that it is anticipated will require to be renewed each year on newly constructed lines. Statistics can be used to good advantage in allotting ties to relatively large units of track. On the smaller units such as the average track section, the "diversity factor" is not large enough to enable statistical control to be used without field inspection."

Another states:

"Our statistics are based on ties used in actual replacement. Ties in newly constructed lines enter into our calculations only in the number of ties in track."

Some roads using statistics built up on the basis of long periods of time as general averages only, adjust for abnormal conditions on the basis of judgment and a comparison of experience on similar districts for similar conditions. Relative to the adjustment of its tie graph for new lines, one road reports as follows:

"In determining the average number of ties per mile used in renewals each year, a correction is applied in cases where new lines have been constructed so that the averages derived furnish a comparison of the renewals on all districts, regardless of the date the lines were constructed—that is, the mileage of new track is not added in a lump the year the line is built but is spread over a fixed period of years in amounts proportionate to estimated tie renewals required for each year. For years prior to 1923, the following per cents were used in determining the mileage to be added:

|                                    |            |
|------------------------------------|------------|
| At the end of the first year ..... | 0 per cent |
| " second year .....                | 0 "        |
| " third year .....                 | 2 "        |
| " fourth year .....                | 3 "        |
| " fifth year .....                 | 5 "        |
| " sixth year .....                 | 5 "        |
| " seventh year .....               | 25 "       |
| " eighth year .....                | 50 "       |
| " ninth year .....                 | 10 "       |

"After the ninth year no correction was applied, it being assumed that the new track then required renewals equally with the older tracks.

"In nearly all of our tracks constructed since 1922, creosoted ties have been used; therefore, commencing with the year 1923, the following per cents are used in determining the miles to be added:

|                                    |            |
|------------------------------------|------------|
| At the end of the first year ..... | 0 per cent |
| " second year .....                | 0 "        |
| " third year .....                 | 0 "        |
| " fourth year .....                | 1 "        |
| " fifth year .....                 | 1 "        |
| " sixth year .....                 | 1 "        |
| " seventh year .....               | 3 "        |
| " eighth year .....                | 5 "        |
| " ninth year .....                 | 7 "        |
| " tenth year .....                 | 8 "        |
| " eleventh year .....              | 9 "        |
| " twelfth year .....               | 10 "       |
| " thirteenth year .....            | 20 "       |
| " fourteenth year .....            | 25 "       |
| " fifteenth year .....             | 10 "       |

"After the fifteenth year, no correction is applied, it being assumed that the new track will then require renewals equally with the older tracks."

On the charts of another road the total mileage of newly constructed lines is not shown until the end of the tenth year. The percentages added to the total mileage at the end of each year on this road are as follows:

|                                    |            |
|------------------------------------|------------|
| At the end of the first year ..... | 0 per cent |
| " second year .....                | 0 "        |
| " third year .....                 | 2 "        |
| " fourth year .....                | 3 "        |
| " fifth year .....                 | 5 "        |
| " sixth year .....                 | 5 "        |
| " seventh year .....               | 20 "       |
| " eighth year .....                | 35 "       |
| " ninth year .....                 | 20 "       |
| " tenth year .....                 | 10 "       |

That the use of statistics as a check on renewal estimates resulting from field inspection, and as a forecast of future renewals, results in tie economies is the opinion of the roads who use statistics in this manner. The reasons given for this fact are as follows:

The Inspector in the field, knowing that his figures will be checked, is naturally more careful in the figures he reports as he knows he will have to substantiate any figures he reports.

The intelligent use of records and statistics is worth a great deal in the selection of ties adapted to the locality in which they are to be used and the traffic they bear. By this method it is possible to arrive at the most economical methods of treatment.

The use of statistics enables the supervising official to keep in touch with the situation and developments that may be occurring.

Statistics are used as a means of controlling maintenance expenditures.

The use of statistics provides a check on renewal requirements which cannot be obtained in any other way and show where investigation is necessary, thereby preventing waste and thus proving their use has an economical value.

### Conclusions

In the foregoing your Committee has endeavored to consolidate the information, furnished by Engineers representing sixty-one railroads in response to the questionnaire, into a story of the methods used for the determination of annual tie renewals, expressions of opinion relative to the use of these methods and possible improvement in them. In this connection your Committee wishes to express its appreciation to those answering the questionnaire, not only for the hearty response but also for the complete yet concise manner in which each phase of the subject was covered.

On these sixty-one railroads, located in all parts of the country, it is to be expected that there is a wide range of conditions which affect methods used for the determination of annual tie requirements. Probably no one method satisfactory for use under all the conditions which obtain can be established. However, your Committee is of the opinion that under most conditions the following general methods will bring about safe and economical control of tie renewals:

1. Field inspection is necessary as a basis for estimating the replacements needed. A field inspection should be made at least once each year, preferably in the Fall. This inspection should be made by roadmaster or track supervisors accompanied by the section foreman, or by the section foreman and checked by the roadmaster or track supervisors, or others directly in charge of and responsible for the safety of the track. Additional check from time to time by other Maintenance officials is very desirable.

2. Ties found on inspection to require replacement should be spotted or branded to so indicate. If on reinspection ties marked for renewal are found which may be retained in service for another year, an additional mark of a different kind may be used to indicate this fact.

3. Ties to be renewed should be reported by some convenient unit such as miles and telegraph poles; miles; miles in main track and individual sidings or yard tracks; sections. Such reporting is an aid to the proper distribution of new ties and indicates localities where reinspection is desirable.

4. Information furnished the Committee indicates that *as a rule* the total number of ties estimated ready for replacement at the time of the original survey is greater than the total requiring renewal shown by the check, and original estimates are usually reduced accordingly. While there is a considerable diversity in the methods used it is quite evident that a check of the original field inspection, by one method or another, is essential to the safe and economical control of tie renewals.

5. If possible a sufficient supply of ties to meet requirements determined by field inspection and check should be kept on hand. When the tie supply is less than the

amount determined by field inspection and check, allotments should be made so that the ties available will be used where needed to make safe operating conditions and where they may be used to best advantage in the judgment of the maintenance officer responsible. A number of methods of allotment have been described in the foregoing.

6. Inspection of a representative number of old ties taken out of track should be made as a check on extravagance in making tie renewals and to ascertain causes of failure of ties of various kinds of woods and treatments. Such inspection should not only be made currently by the track supervisors or roadmaster, but also from time to time by Division and Maintenance Officers or Special Inspectors. It is believed more can be accomplished toward obtaining uniformity of judgment by all foremen, by examining with them ties taken out of track, than in any other way.

7. Section foremen should not be permitted to remove ties in excess of the yearly allotment. Should more ties be needed, in the opinion of the section foreman, than provided by the allotment, the situation should be called to the attention of the roadmaster or track supervisor, and through him authority obtained for the additional ties. Section foremen should be allowed some latitude in the removal of ties at variance with the marking for renewal, to provide for the replacement of ties broken, or otherwise injured so as to destroy their usefulness. Further deviation from the spotting may be found necessary throughout the renewal season as the ties are uncovered, but such deviation should be authorized from time to time by the roadmaster or track supervisor who should inspect a considerable per cent of the ties with the section foreman before actual renewal is made.

8. Special Inspectors chosen for their knowledge and experience instructed in the management's policy and the standard of maintenance required, may be used with resulting uniformity of practice. Such Inspectors are successfully used under certain plans of field inspection and estimation of tie requirements. Specially trained Inspectors may be used to advantage for the inspection of a representative number of old ties taken out of track, as a check on extravagant renewals and for the collection of data as to the causes of failure of ties of various treatments and kinds of wood. Special Inspectors may also be used for the annual check of tie test track.

9. Tie service statistics should not be used in lieu of field inspection but are of real value as a check on the renewal estimates resulting from field inspection and as a guide to the trend of future renewals. From detailed statistics average service life of ties of various kinds and treatments may be calculated. The proper use of statistics should result in efficiency and economy in the renewal practice.

## REPORT OF COMMITTEE IV—RAIL

|                                 |                  |                                      |

*To the American Railway Engineering Association:*

Your Committee respectfully presents herewith its report covering the following assignments:

1. Revision of Manual (Appendix A).
2. Further research, including details of mill practice and manufacture as they affect rail quality and rail failures, giving special attention to transverse fissure failures, collaborating with the Rail Manufacturers' Technical Committee (Appendix B).
3. Compilation of statistics of all rail failures, making special study of transverse fissure failures (Appendices C, D and E).
4. Cause and prevention of rail battering, collaborating with Committee V—Track (Appendix F).
5. Economic value of different sizes of rail (Appendix G).
6. Rail lengths in excess of thirty-nine feet (Appendix H).
7. Information on tests of alloy and heat-treated carbon steel rail (Appendix I).
8. Redesign rail sections heavier than 100-lb. per yard so as to obtain the most economical distribution of metal with the maximum strength of section (Appendix J).
9. Heat treating of rail ends to reduce wear (Appendix F).
10. Design joint bars for RE rail sections as developed (Appendix K).

### Action Recommended

1. That the revisions and additions to the Manual recommended in Appendix A be approved for publication in the Manual as recommended practice.
2. That progress reports on subjects 2 to 10 inclusive in Appendices B to K be received as information and that these subjects be continued with the exception of No. 6—"Rail Lengths in Excess of 39 Feet" which it is recommended be discontinued for the present.

Respectfully submitted,

THE COMMITTEE ON RAIL,  
EARL STIMSON, *Chairman*.

## Appendix A

## (1) REVISION OF MANUAL

A. F. Blaess, Chairman, Sub-Committee; W. C. Barnes, N. J. Boughton, C. B. Bronson, E. E. Chapman, W. A. Duff, L. C. Fritch, F. M. Graham, C. R. Harding, G. W. Harris, W. H. Penfield, G. J. Ray, C. P. VanGundy, W. P. Wiltsee, J. B. Young.

## DEFINITIONS

The following changes and additions beginning at page 135 of the Manual, are recommended:

Add note after definition for Alloy Steel:

"The above definitions for iron and steel apply to joint bars, bolts and spring washers as well as rail."

Insert in alphabetical order under heading Manufacture:

COBBLE.—"In a rolling mill, any steel which has become bent or twisted so that it cannot be finished by rolling is termed a "COBBLE".

HOTBED.—"A series of skids on which rails are placed for cooling after rolling, cambering and sawing."

Substitute—

CROP END.—"A piece cut from the end of a bloom or rail during manufacture."

Remove the word "with" in definition of Compound Fissure, line 2, page 16 of 1932 Supplement to Manual, Bulletin 347.

## RAIL SPECIFICATIONS

The following corrections or changes are recommended:

Section 6, page 149: A request having been received for height of drop to be used in applying drop test to 70-80-lb. rail the following addition is recommended:

"For 70-80-lb. rail inclusive.....17 ft."

Section 12, page 150: Add "or drawings" after word "templates" in line 2.

Substitute: "width" for word "length", line 4.

Section 20 C, page 152: In order to avoid payment for weight in excess of the one-half of one per cent overrun allowed in Section 13, it is recommended that the words "subject to limitation of Section 13" be added making this sub-section read—

"Rail accepted will be paid for according to actual weight subject to the limitations of Section 13."

## DRILLING OF RAILS

The following corrections or changes are recommended:

(1) Paragraph 1, page 162: Elimination of this general recommendation as unnecessary and inadvisable, as specific directions for drilling are elsewhere given. This includes the necessary renumbering of the succeeding paragraphs.

(2) Page 162: Revise data under heading "Application of Recommended Rail Drilling to Standard Rail Sections," to include only the present standard sections, as follows:

| <i>Weight of<br/>Rail, Lb.</i> | <i>Type of<br/>Rail</i> | <i>Height of Bolt Hole<br/>Above Base of Rail,<br/>Inches</i> |
|--------------------------------|-------------------------|---------------------------------------------------------------|
| 90 .....                       | RA-A                    | 2 37/64                                                       |
| 100 .....                      | RE                      | 2 45/64                                                       |
| 112 .....                      | RE                      | 2 7/8                                                         |
| 131 .....                      | RE                      | 3 3/32                                                        |

This eliminates sections which are no longer standard and adds data for the 112-lb. and 131-lb. RE sections.

(3) Page 162: Revise the sentence, "The standard drilling for rails should be as shown in the following diagrams" to read, "The standard drilling for standard rails up to and including 100-lb. per yard should be as shown in the following diagrams".

## SPECIFICATIONS FOR HIGH CARBON STEEL AND FOR QUENCHED CARBON STEEL JOINT BARS

(1929 Manual, pages 166-169)

In order to keep the same terms in all Rail Committee specifications, substitution of the word "heat" for "melt" wherever the latter is used is recommended.

While title of these specifications refers to Joint Bars there are a number of references to splice bars on page 169. Recommend uniform use of the term "Joint Bars."

Paragraph 13, page 169, last line: Recommend quenching temperature be shown in degrees Fahr. and degrees Centigrade enclosed in parentheses.

## REVISION OF FORM 402 A

Following changes are recommended, pages 180-181 of Manual: Face of form, item 38—Change "Horizontal Fissure" to "Horizontal Split Head."

Back of form—Under "Description of Rail Failures", add new definition 1 B as given on page 16, Bulletin 347: (B) "COMPOUND FISSURE—A horizontal split head which in developing extends into a plane other than horizontal".

Designate definition for "Ordinary Break" by (C) instead of (B) and in third line of same substitute word "compound" for word "horizontal".

4. "SPLIT HEAD"—Change title to "Vertical Split Head".

Add a new definition 5 as given on page 16, Bulletin 347: "HORIZONTAL SPLIT HEAD"—"A horizontal progressive fracture originating in the interior of the head of rail usually indicated on the side of head by longitudinal seam or crack and flow of metal".

Renumber definitions 5, 6 and 7 as 6, 7 and 8.

Eliminate the word "Internal" under the cut of "Internal Transverse Fissure".

## Recommendations

1. That the changes and additions recommended above under heading "Definitions" be approved for publication in the Manual.

2. That the corrections or changes recommended above under heading "Rail Specifications" be approved for publication in the Manual.

3. That the corrections or changes recommended above under heading "Drilling of Rails" be approved for publication in the Manual.

4. That the revisions recommended above under heading "Specifications for High Carbon Steel and for Quenched Carbon Steel Joint Bars" be approved for publication in the Manual.

5. That the revision of Form 402-A—Report of Rail Failure in Main Track, recommended above under heading "Revision of Form 402-A" be approved for publication in the Manual.

## Appendix B

**(2) FURTHER RESEARCH, INCLUDING DETAILS OF MILL PRACTICE AND MANUFACTURE AS THEY AFFECT RAIL QUALITY AND RAIL FAILURES, GIVING SPECIAL ATTENTION TO TRANSVERSE FISSURE FAILURES, COLLABORATING WITH RAIL MANUFACTURERS' TECHNICAL COMMITTEE**

Earl Stimson, Chairman, Sub-Committee; A. F. Blaess, W. C. Barnes, C. B. Bronson, E. E. Chapman, R. Faries, J. V. Neubert, G. J. Ray, W. P. Wiltsee, L. Yager.

For a general outline or program of the Joint Investigation, being carried on at the University of Illinois by the Rail Committee and by the Rail Manufacturers' Technical Committee to determine the cause of and remedy for transverse fissure and other rail failures, reference is made to the Committee's report to the March 1932 Convention (A.R.E.A. Proceedings 1932, Vol. 33, pages 557-8).

This investigation is now in its third year and definite progress is being made. The laboratory work is continuing but greater emphasis is now being placed on the second stage of the investigation, namely, the field tests of rails that were placed in service on the B.&O. and A.T.&S.F. Special equipment has been obtained for the intensive study of the behavior of these rails in service and for the recording of the service stresses to which they are subjected. This work will be followed by a correlation of the laboratory and field test results.

These tests are for the purpose of, first, determining the presence of any transverse fissure developments in the rails and, second, measuring the magnitude of the wheel loads which are actually met in service. The tests for transverse fissures are made by the drop-of-potential method, using apparatus mounted on a car specially designed and constructed for these tests. A scratch extensometer was developed by members of the research staff to measure the elongation of the base of the rail under moving trains from which the wheel loads are calculated.

A Metallurgist has been added to the staff to make study of mill records of the test rollings in an endeavor to tie up abnormalities in chemistry or in mill practice with results of laboratory tests already made on the finished test rails.

This work will be continued and expanded during the coming year and your Committee is pleased to report substantial progress.

## Appendix C

**(3) RAIL FAILURE STATISTICS FOR 1932**

By W. C. Barnes, Engineer of Tests, Rail Committee

The Rail Failure statistics for the year ending December 31, 1932, appearing in this report have been compiled in accordance with the standard method of basing the failure rates on mile years of service in track.

The reported tonnages and track miles of rollings for 1927 and succeeding years embodied in these statistics are as follows:

| <i>Year Rolled</i> | <i>Tons</i> | <i>Track Miles</i> |
|--------------------|-------------|--------------------|
| 1927 .....         | 1,775,594   | 10,479             |
| 1928 .....         | 1,682,899   | 9,742              |
| 1929 .....         | 1,707,783   | 9,709              |
| 1930 .....         | 1,210,343   | 6,852              |
| 1931 .....         | 620,483     | 3,521              |
| Totals .....       | 6,997,102   | 40,303             |

Table 1 shows the average failures per 100 track miles of rail in service which occurred in one to five years service of all rail reported, from all mills, together with results taken from previous reports which include both Bessemer and Open Hearth rail. The 1927 rollings, whose period of observation is now concluded, show an average of 112.4 failures per 100 track miles during the five year period, a decrease of 18.9 failures under those reported last year for the 1926 rollings but substantially the same rate as previously reported for rollings of 1922 to 1925 inclusive.

Fig. 1 shows diagrammatically the five year averages from Table 1.

FIG. 1

Table 2 presents a summary from 20 annual reports showing track miles of rail originally laid and total failures in addition to the failures per 100 average track miles of rail in service for periods of one to five years.

Table 3 gives the failure rates of rail from each of the mills for rollings since 1908 for one to five year periods.

Fig. 2 shows diagrammatically the data from Table 3. Abnormal increases in failure rates in the 1927 as compared with the 1926 rollings, from Maryland and Algoma mills are indicated.

Table 4 presents a recapitulation of the performances during the five year period of rail rolled at each of the mills. In this table the original track miles laid from the various rollings are given as information, the failure rates being computed from the average track miles in service during the period.

Fig. 3 presents diagrammatically the average "per year" failure rates per 100 average track miles in service of the 1927 to 1931 rollings from the various mills from Table 4. These rates do not take into consideration the traffic carried. Inland shows the lowest failure rate of 4.8 followed closely by Minnequa with a rate of 7.1 and Gary with a rate of 9.2. Maryland shows the highest failure rate of 36.4 closely followed by Steelton and Ensley. The average rate for all mills is 17.4. Algoma and Dominion mills have not been included in Fig. 3 and 4 because of the comparatively small tonages reported.

Fig. 4 rates the performances of the mills from the same data that underlie Fig. 3 except that traffic density factors have been introduced into the final computation. From the annual freight gross ton miles per mile of main track of each reporting road applied to its track mile years of rail of each of the 1927 to 1931 rollings from any given mill, the weighted average traffic over all of that mill's rail which was reported on, was determined. In like manner the weighted average traffic over all rail from each of the

FIG. 2.—Record of Failures per 100 Track Miles for Five Years' Service for Rollings from 1908 to 1927.

other mills was separately determined. The mill whose rail was subjected to the lightest traffic was then considered to have unit traffic density and relative traffic density factors were determined for each of the other mills, which were applied to the failure rates of the respective mill outputs given in Fig. 3. No claim is made that this method of rating is entirely accurate but it does give more consideration to the work which the rails from the various mills were called upon to perform than does the method of rating underlying Fig. 3 which takes no account of traffic.

FIG. 3.—Average Failure Rates for the Rollings of 1927 to 1931 Inclusive, Classified by Mills.

FIG. 4.—This Diagram is presented as information only. It shows Average Failure Rates for the Rollings of 1927 to 1931, inclusive, Classified by Mills, changed from those presented in Fig. 3.

The use of traffic density factors has resulted as follows: Inland remains in first place with the lowest failure rate, Gary has moved up into second place very closely followed by both Minnequa and Edgar Thomson and Ensley has moved to the lowest rank. The average traffic on Steelton and Maryland rails have improved their position in respect to Ensley.

FIG. 5.—Accumulated Failures for Rollings from 1927 to 1931 Inclusive.

Fig. 5 presents diagrammatically the "total" failure rates by mills and by years rolled from Table 4. The improvement in Ensley rails of the 1928 to 1931 rollings as compared with the 1927 rolling is marked.

Table 5 shows the average weights of rail from the various mills and from all mills included in these statistics. The average weight for all mills is substantially constant for the 1929 to 1931 rollings.

TABLE 1  
AVERAGE FAILURES PER 100 TRACK MILES—ALL MILLS

| Year<br>Rolled | Years Service |      |       |       |       |
|----------------|---------------|------|-------|-------|-------|
|                | 1             | 2    | 3     | 4     | 5     |
| 1908           |               |      |       |       | 398.1 |
| 1909           |               |      |       | 224.1 | 277.8 |
| 1910           |               |      | 124.0 | 152.7 | 198.5 |
| 1911           |               | 77.0 | 104.4 | 133.3 | 176.3 |
| 1912           | 28.9          | 32.1 | 49.3  | 78.9  | 107.1 |
| 1913           | 12.5          | 25.8 | 44.8  | 69.5  | 91.9  |
| 1914           | 8.2           | 19.8 | 32.9  | 50.9  | 74.0  |
| 1915           | 8.9           | 19.0 | 34.2  | 53.0  | 82.4  |
| 1916           | 11.8          | 29.2 | 47.7  | 70.6  | 105.4 |
| 1917           | 21.6          | 38.9 | 66.0  | 110.5 | 137.0 |
| 1918           | 8.9           | 27.6 | 54.0  | 92.8  | 125.4 |
| 1919           | 14.8          | 39.4 | 73.7  | 104.8 | 115.7 |
| 1920           | 14.2          | 32.4 | 63.1  | 84.5  | 119.6 |
| 1921           | 10.9          | 34.9 | 56.9  | 70.9  | 98.9  |
| 1922           | 15.9          | 34.8 | 55.2  | 80.4  | 110.0 |
| 1923           | 14.3          | 33.2 | 57.6  | 86.0  | 114.1 |
| 1924           | 14.0          | 33.4 | 58.3  | 82.0  | 110.7 |
| 1925           | 15.5          | 36.6 | 58.3  | 76.6  | 110.7 |
| 1926           | 17.1          | 41.2 | 64.6  | 102.6 | 131.3 |
| 1927           | 18.4          | 37.7 | 69.5  | 94.6  | 112.4 |
| 1928           | 11.0          | 28.0 | 45.8  | 57.4  |       |
| 1929           | 14.1          | 36.8 | 55.9  |       |       |
| 1930           | 7.8           | 12.8 |       |       |       |
| 1931           | 9.1           |      |       |       |       |

TABLE 2  
SUMMARY FROM TWENTY ANNUAL REPORTS SHOWING TRACK MILES ORIGINALLY LAID, TOTAL FAILURES  
AND FAILURES PER 100 AVERAGE TRACK MILES IN SERVICE

| Service               | Five Years                 |               |                    | Four Years                 |               |                    | Three Years                |               |                    | Two Years                  |              |                    | One Year                   |              |                    |

## Appendix D

### (3) TRANSVERSE FISSURE STATISTICS

By W. C. BARNES, Engineer of Tests, Rail Committee

These statistics constitute a cumulative record of 65,281 transverse fissure failures which have been reported up to and including December 31, 1932. They include all fissured rails reported whether located by actual breakage in track or detected before breakage by inspection or test.

Table 1 corresponds with Table 1 of last years report and shows the number of transverse fissure failures reported by each of 54 roads and the years in which such failures occurred. The service and detected failures which occurred each year are listed separately and the combined accumulated totals to December 31, 1932 are given. The total failures for any year on any road can be obtained by adding the service failures and the detected failures for that year.

The accumulated grand total of fissure failures, service and detected, reported to December 31, 1932 from all rollings was 65,281 or an addition during the year of 7054, which is 427 less than were reported in 1931. This decrease is accounted for by a reduction of 171 service failures and 256 detected failures. This decrease in total service and detected failures, as will be seen from Fig. 1, is the first that has occurred since the year 1924.

Fig. 1 presents graphically the total fissure failures reported each year. The dotted curve includes "detected" fissure failures while the solid curve excludes them. The broken line curve presented this year for the first time shows the detected fissure failures only. The change in slope of the curve of actual service failures co-incident with the start of Detector Car work in 1929 is noteworthy. The downward slope, during the year 1932, of the dotted curve showing all fissure failures no doubt results from the detection work carried on during that and previous years and from decreased traffic.

Table 2 corresponds with Table 2 of last years report. It shows all transverse fissure failures accumulated from year rolled to December 31, 1932, for each years rollings from each mill, unweighted by tonnage output of mills, by density of traffic or by years of service. This Table is most useful in comparing the failures in the

various years rollings from any one mill. Study of this table will disclose wide variations in the total failures in the different years rollings of several of the mills. The most recent example of this is in the 1929 rollings from Sparrows Point (Maryland), compared with its earlier and later rollings.

FIG. 1.—Total Fissure Failures Reported Each Year

Fissure failures reported since 1924 as occurring in the first year of service are as follows:

|     |                                                |
|-----|------------------------------------------------|
| 29  | Failures in 1925 from 1925 Rollings, All Mills |
| 50  | " " 1926 " 1926 " " "                          |
| 114 | " " 1927 " 1927 " " "                          |
| 58  | " " 1928 " 1928 " " "                          |
| 106 | " " 1929 " 1929 " " "                          |
| 33  | " " 1930 " 1930 " " "                          |
| 32  | " " 1931 " 1931 " " "                          |
| 3   | " " 1932 " 1932 " " "                          |

The small number of first year failures in the 1932 rail is no doubt influenced by light traffic as well as by the small tonnage of 1932 rail purchased.

Table 3 corresponds with Table 3 of last years report and shows the rate of accumulated failures on selected roads per 100 original track miles per year from year rolled to December 31, 1932. The data included are for the rollings of 1925 to 1929 inclusive and are segregated by mill and by year rolled. No account is taken in this table of differences in density of traffic over the rails from the various mills.

Table 3 includes a total of 11,431 fissure failures which occurred in 37,239 miles of track. Colorado, Inland, Gary and Carnegie mills show the lowest average accumulated failure rate per 100 track miles per year from date rolled to December 31, 1932, the respective rates being 0.41, 2.48, 2.48 and 3.62. Steelton, Lackawanna, Tennessee and Maryland produced the higher rates of 7.96, 8.16, 11.02 and 39.93 respectively, the high rate of Maryland being due to the excessive rate of 105.53 produced by its 1929 rollings.

Fig. 2 shows graphically the average rates of failure by mills from Table 3.

Fig. 3 shows graphically the average rates of failure by mills from Table 3 modified by the application of average traffic density factors. The method of obtaining these factors has been explained in detail in preceding reports.

The weighting for relative traffic density has improved the rates of those mills whose rails carried the heavier traffic and has resulted in putting Carnegie in third rank instead of Gary.

TABLE 1  
TRANSVERSE FISSURE FAILURES BY RAILROADS AND YEAR FAILED

| Railroad                     | Prior | Service Failures |      |      |      |      |                 |      |      |      |             |      |               | Detected Failures** |          |       |     |      | Grand Total |
|------------------------------|-------|------------------|------|------|------|------|-----------------|------|------|------|-------------|------|---------------|---------------------|----------|-------|-----|------|-------------|

\* Data given for 1930 covers 11 months from February 1st to December 31st. Prior to 1930 each year's data covers 12 months from February 1st. Subsequent to 1930 each year's data covers 12 months from January 1st.

\*\* Detection methods first used to any extent in 1929.

TABLE 2

ACCUMULATED TRANSVERSE FISSURE FAILURES REPORTED TO DEC. 31, 1932 BY YEAR ROLLED AND BY MILL  
(Includes fissured rails detected before actual failure in track).

| Years Rolled | Unknown |      |       | Algoma |      |       | Saucon (Bethlehem) |      |       | Cambria (Bethlehem) |      |       | Edgar Thomson (Carnegie) |      |       | Minnequa (Colorado) |      |       | Dominion |      |       | Krupp (German) |      |       |

TABLE 2—Continued

ACCUMULATED TRANSVERSE FISSURE FAILURES REPORTED TO DEC. 31, 1932 BY YEAR ROLLED AND BY MILL

(Includes fissured rails detected before actual failure in track)

### OPERATING RESULTS OF THE A.R.A. RAIL FISSURE DETECTOR CAR

By W. C. BARNES, Engineer of Tests, Rail Committee

On November 14, 1933 the A.R.A. Detector Car completed its fifth year of operation under the direction of the Rail Committee, having travelled on its own wheels a total of 50,000 miles and tested 23,181 track miles of rail in all sections of the country. Approximately 6,600 track miles were tested during the last year.

With no change in the per diem rental charge for the car (\$85.00 per day independent of mileage tested) our total amount billed against lessee roads per track mile tested has been constantly reduced due to improvement in testing methods. Within the last two years this reduction has amounted to practically 28 per cent, resulting in a remarkably low cost to the railroads per mile tested.

The average track miles tested per testing day for the last 3,500 miles tested was close to 27. It is now safe to say that the average track miles that can now be tested per day varies between 20 and 27 miles, depending on the density of traffic and condition of the rail tested, with an efficiency of testing superior to any heretofore obtained.

The American Railway Association has recently approved the purchase of a more substantial car to house the detecting equipment and it is expected that this will still further decrease the cost of testing through increase in permissible speed when running light between test locations, clearing for traffic, etc.

The demand for A.R.A. testing service has been little affected by general business conditions and we are again able to say that the car has not yet been idle a single day for lack of business.

## Appendix F

### (4) CAUSE AND PREVENTION OF RAIL BATTERING, COLLABORATING WITH COMMITTEE V—TRACK

#### (9) HEAT TREATING OF RAIL ENDS TO REDUCE WEAR

F. M. Graham, Chairman, Sub-Committee; W. J. Backes, W. C. Barnes, W. A. Duff, B. Herman, E. E. Oviatt, W. H. Penfield, R. T. Scholes, J. R. Watt, C. E. Weaver, J. E. Willoughby.

The study of Subject 4—"Cause and Prevention of Rail Battering", has progressed to the point where it may be stated that the cause of rail battering is due to the very high unit static pressure between the wheel and the rail combined with impact blows of wheel on the rail. Causes which accelerate battering are:

1. Heavy wheel loads.
2. Small wheels.
3. Large joint openings.
4. Soft rail.
5. Difference in height of rails in joint.
6. Spring condition of equipment.
7. Increase of weight on low rail of curves.
8. Small radius across top of rail.
9. Poor maintenance of joint parts.

Causes Nos. 3, 4, 5, 6, 8 and 9, can be corrected or modified.

It is now believed that the most effective way to reduce rail battering consists in making the rail ends more resistant to deformation by a suitable heat treatment.

Various methods of heat treating rail ends are now being tried as follows:

1. Quenching by air blast in rail mill to desired hardness.
2. Heating rail ends in track with (free held) acetylene torch, quenching with water to 200 degrees Fahr. and drawing to desired hardness by torch heating.
3. Heating rail ends in track with acetylene torch held in carriage with controlled time of heating and limited quenching, leaving residue of heat to draw to desired hardness.
4. Preheating with gasoline stove followed by heating with electric arc moving over surface to be heated by cam movements. Heating automatically stopped when a given number of watts have been used. Quenching with circulating oil and surface then protected by insulating pad for a few minutes.

Method No. 1 has been used experimentally in a very limited way and little field testing has been done.

Method No. 2 has been very extensively used for a number of years on the C.M.St.P. & P.R.R., with very good results. Other roads are now using this method quite extensively.

Method No. 3 has been used only in a very limited test on the Pennsylvania R.R.

Method No. 4 has been used quite extensively during the past year. This method is patented and work is done under contract.

All methods aim at bringing the top of the ends of the rails to a Brinell hardness of about 350 to 400 and to a depth of something over  $\frac{1}{4}$  in.

All methods quench from a temperature of about 1500 deg. Fahr.

Methods No. 1 quenches with an air blast and produces a variable degree of hardness over a considerable length and depth from the rail end.

Methods Nos. 2, 3 and 4, confine the hardening to 2 to 3 in. from the rail end.

The heat treatment of steel to obtain desired results involves much care and accuracy in the method. Attention must be given to the chemistry of the steel, the size and shape of the piece, the time of heating and temperature at the quench, the quenching medium and time of its application, the temperature at which it is drawn, also time of drawing.

In the case of rail end heat treating, the above difficulties are increased by the absorption of heat by the metal outside of the heat treated zone.

If the steel is heated for the quench too rapidly, the surface reaches the quenching temperature without sufficient penetration, and if heated too slowly, the heat treating effect is carried too deep.

If rail ends are not drawn before traffic passes over them, the resultant extreme hardness may cause the top corner at the end of the rail to shatter.

All of the above discussion applies to new rail or cropped rail; and this practice is now being used on the C.M.St.P.&P.R.R., C.&O.Ry. and the Erie Railroad with good results.

Heat treating is now being applied to welded rail ends.

Two graph sheets are attached showing the comparative results of heat treated and untreated rail ends.

Plate "A" shows results where the third method was used.

It will be noted that the ends were treated  $5\frac{1}{2}$  months after the rail was laid, or after 23,000,000 tons had passed over it.

These measurements show that farther batter was practically stopped by the heat treatment.

Plate "B" shows results where the second method was used. This rail was heat treated as it was laid. On account of rust and mill scale interfering with measurements,

Plate A

Plate B

the earliest graph shown was from measurements made the day after rail was laid and during which time some batter occurred.

While both of these graphs show the true profile as of date of measurement, it is noted that in the case of the heat treated ends, the rail has apparently raised. This is due to the fact that the straight edge gage used was supported at points 3 in. from the delivering end and 7 in. from the receiving end. Both of these points are outside of the heat treated zone and where the rail received the normal untreated wear leaving the heat treated portion relatively high due to the slower rate of wear on the heat treated areas.

If the heat treated portions become undesirably high, they can be readily ground down at small cost.

### Recommendations

In view of the satisfactory experience of heat treating rail ends on the C.M.St.P.&P.R.R., C.&O.Ry., Erie Railroad, and Penna. R.R., also considerable experimental testing on several other roads, where results have been most encouraging, it is recommended that the heat treating of rail ends be generally followed in the case of new rail, cropped rail, or where rail batter has not progressed to an objectionable extent.

It is farther recommended in connection with the above that where necessary the top of rail ends be ground to the same height.

Some of the above mentioned methods of heat treating rail ends have only been available for a short time, and their relative merits and costs are not now known and should be farther studied.

It is urged that extensive tests by railroads generally of the practice of heat treating rail ends be undertaken and that information including results and costs by various methods be made available.

It is recommended that the subject be continued.

### Appendix G

#### (5) ECONOMIC VALUE OF DIFFERENT SIZES OF RAIL

J. M. Farrin, Chairman, Sub-Committee; Lem Adams, J. B. Baker, W. C. Barnes, F. L. C. Bond, R. Faries, C. R. Harding, C. W. Johns, H. C. Mann, G. J. Ray, A. N. Reece, H. R. Thomas, W. P. Wiltsee.

A great deal of work was done on this assignment this year, and percentages derived showing effect of size of rail on the track structure and tentative report prepared but no agreement has been reached upon quantitative value expressed in money to place upon these percentages, so it is considered best to withhold the report for more definite information.

Before final report can be submitted it may be necessary to set aside test tracks made up of the different rails to determine the monetary value of the various percentages.

The Committee therefore reports progress and recommends that the assignment be continued.

## Appendix H

## (6) RAIL LENGTHS IN EXCESS OF THIRTY-NINE FEET

By R. T. SHOLES, Chairman, Sub-Committee

The experience of the Rail Committee at the time the 39-ft. standard length was adopted indicated that it was necessary to negotiate with the committee representing the steel manufacturers in order to study problems or difficulties connected with manufacture and use of the length under consideration. The 39-ft. standard length was generally adopted by the railroads in 1925, and specification providing for same was accepted by the manufacturers without extra charge over the base price.

In taking up consideration of the desirability of adopting a standard length in excess of 39 ft., the Committee has felt that a similar procedure is essential to reach a definite agreement.

Naturally the committee representing the manufacturers desires definite advice as to what the preference of the majority of purchasers is in this respect and also, which is most important to them, whether this standard length would remain undisturbed for a considerable period of time, owing to the fact that the steel companies are confronted with a heavy plant investment in order to furnish longer length rails, and are reluctant to make such investment unless they have assurance that a new standard length is going to remain fixed for some years.

The Committee, in handling this assignment, accordingly undertook to develop the sentiment of various Class I railroads on the subject, and the reports received indicate a preference for standard lengths as follows:

| 37 roads favor 39 ft. standard length. |   |   |    |   |   |
|----------------------------------------|---|---|----|---|---|
| 9                                      | " | " | 45 | " | " |
| 3                                      | " | " | 48 | " | " |
| 1                                      | " | " | 50 | " | " |
| 5                                      | " | " | 66 | " | " |
| 1                                      | " | " | 75 | " | " |
| 6                                      | " | " | 78 | " | " |
| 1                                      | " | " | 79 | " | " |

—  
Total of 63 roads voted to date.

Under the circumstances the Committee feels that it is quite clearly indicated that the majority of railroads are not prepared at this time to present to the manufacturers a request for standard length in excess of 39 ft. It is therefore recommended that the existing standard length be continued for the present. In reaching this conclusion the Committee has in mind the existing business conditions and the undesirability of having the steel companies make heavy plant investments at this time.

The Committee, however, feels as a result of the information received from various railroads as to their experience with rail lengths in excess of 39 ft. that so far as service conditions are concerned, an increased standard length is entirely feasible and practicable and offers considerable promise of improved track and reduced maintenance cost on account of the reduced number of joints to be maintained.

It is highly desirable for the various railroads to continue experiments with long-length rails to obtain further actual service results as a matter of general information to all concerned. The points particularly involved, on which definite information is desired, are as follows:

1. Car supply for handling long rails.
2. Relative cost of loading, unloading and placing in track.
3. Proper expansion allowance.

4. Maintenance of uniform expansion in service.
5. Prevention of rail creeping.
6. Maintenance of line and surface, especially under high temperatures, and prevention of excessive joint gaps under low temperatures.
7. General economy of long-length rails as compared with present 39 ft. standard.
8. Information for each rail mill on changes in plant construction which would be involved if a longer standard length were finally adopted.

The Committee expresses the hope that this experimental work will be continued so that in the course of a few years the railroads will be in a position to unite on a request for a standard length of rail which will be acceptable to a large majority of the railroads of the United States and Canada.

### Recommendation

The Committee recommends that this report be received as information and the subject discontinued for the present.

### Appendix I

#### (7) TESTS OF ALLOY AND HEAT TREATED CARBON STEEL RAILS

By W. C. BARNES, Engineer of Tests.

Owing to the small amount of alloy and heat treated carbon steel rail purchased during 1932, no data were presented in last year's report on this subject. The 1933 purchases of these special rails were also very light, but to preserve our record the following data are presented:

#### ALLOY STEEL RAILS—INTERMEDIATE MANGANESE

##### PURCHASES OF INTERMEDIATE MANGANESE RAIL

A questionnaire was sent to the roads listed in the above tabulation. The following additional data regarding service results obtained with intermediate manganese rail were received from the Atchison, Topeka & Santa Fe; the Boston & Maine; Canadian National; Illinois Central; Kansas City Southern; Missouri-Kansas-Texas; New York Central; Northern Pacific, and Southern Railway.

Question 1—Tonnage purchased during 1932 and 1933 not previously reported:

A.T. & S.F.:—

| <i>Year</i> | <i>Company</i> | <i>Plant</i> | <i>Wgt. per Yd.</i> | <i>Section</i> | <i>Tons</i> |
|-------------|----------------|--------------|---------------------|----------------|-------------|
| 1932 .....  | Colorado       | Minnequa     | 110                 | R.E.           | 17973       |
| 1933 .....  | "              | "            | 110                 | R.E.           | 20421       |
| 1933 .....  | "              | "            | 130                 | R.E.           | 814         |

No purchases reported by other roads.

Question 2—Have any changes been made in composition or mill practice for the rails purchased by your railroad during the past two years?

No changes reported.

Question 3—Give results of any special laboratory tests or investigations on new rails that you may have carried out, either in cooperation with the steel mills or in your laboratory.

A.T. & S.F. reports its investigation not yet completed. Other roads report no special tests.

Question 4—Present contours or tabulated results of investigations on wear of rail heads on curves and also tangent track, comparing intermediate manganese with standard open hearth rails in similar service.

What conclusions have you arrived at, based on your general observations of the two classes of steel?

A.T. & S.F.—No contours. No definite conclusion.

Boston & Maine—

Records indicate that medium manganese rails develop batter at a more rapid rate than carbon steel rails. Have had a larger number of split head rails due to segregations.

Illinois Central—We had a small amount of 90-lb. intermediate manganese rail, some of which replaced plain carbon steel rail on a 5 degree curve. Accurate comparison of the wear of the two kinds of steel could not be made as contour measurements had not been taken of the plain carbon rail. We estimate, however, that there was an increase in length of service of the intermediate manganese rail of about 25%.

An excessive number of split heads has developed in some of our intermediate manganese rail indicating that the steel is not of uniform composition. Due to varying traffic, the introduction of track oilers and other causes we are not able to make comparisons of 110-lb. rail.

Kansas City Southern—Measurements continue to show no appreciable difference in wear on inside and outside of a 1° and 5° curve.

Missouri-Kansas-Texas—Inspection in July 1932 showed insufficient wear to warrant conclusions as to relative merits of intermediate manganese and standard O.H. rails.

New York Central—General study of head wear shows that medium manganese rails are resisting abrasion on high side of curves to greater extent than standard open hearth, and also somewhat less flow on low rails of curves.

Southern Railway—Wear in 100 lb. Intermediate Manganese Rail and Standard Carbon Rail installed between Mileposts 710 and 714 near Edwardsville, Ala., Birmingham Division. Rail Installed in May and June 1929 were measured in March 1932.

The information obtained tends to indicate that intermediate manganese rail wears more rapidly than our standard steel rail.

Question 5—Present general or specific data on the batter and chipping of rail ends, comparing intermediate manganese and standard open hearth rails.

A.T. & S.F.—After five years under similar conditions, Intermediate manganese rail shows 1.7 per cent of chipping against 15 per cent for standard open hearth. Rail batter approximately the same on both.

New York Central—There is no noticeable difference in batter or chipping as shown by general observations.

Boston & Maine—See answer to Question 4.

Illinois Central—No difference with respect to chipping has been observed.

Canadian National—No definite conclusions yet.

Question 6—Table of Intermediate Manganese Rail Failures, summarizing total failures since rail was laid, to January 1, 1933.

Question 7—How do intermediate manganese and standard open-hearth rail failures compare, giving detailed statement, or general conclusions.

### A.T. & S.F.

Data similar to that for Question 6 is here given for standard open-hearth rail.

Have had no transverse fissure failures in intermediate manganese rail to date.

### Boston & Maine

In the years 1927, 1928, 1929 and 1930, 48360 tons of standard open hearth carbon rails were purchased. The failures in this type of rail to January 1, 1933 have been less than .15 per cent. The failures in the 100-lb. intermediate manganese have been approximately .40 per cent and in the 130-lb. intermediate manganese approximately .70 per cent.

### Canadian National

The following shows comparative failures in intermediate and carbon steel rails which have been in track approximately the same time.

|                           |        |      |       | <i>Average rate of failure per 100 track miles per year</i> |

### Kansas City Southern

For all intermediate manganese rail in track the failures to January 1, 1933 average one failure per 3270 ton-years in service. Open-hearth rail laid in the same years show one failure per 17000 ton years. It should be remembered, however, that the intermediate manganese rail was all laid on curves of two degrees and over, which should be taken into consideration in comparison of failures.

### Northern Pacific

Owing to the presence of horizontal split heads in intermediate manganese rail, the failure rate seems somewhat excessive. In the comparative statement under Question 6 a very large proportion of the broken standard composition rails broke in a long tunnel through the bolt holes and where this is taken into consideration the showing of the intermediate manganese 130 lb. compared with the standard rail would be as unfavorable to the former as it is in the case of the 100 lb. section.

### New York Central

In comparing rail failures in medium manganese with open hearth rails, the general statement applies that fissures are considerably less numerous in medium manganese rails than in standard open hearth rails. Head failures in the former are very much higher, of which 75 per cent or more are horizontal crushed or split heads in the receiving end of the rail, usually about  $\frac{1}{2}$  inch deep by 2 inches lengthwise of the head, due largely to internal shattering, plus the pounding which the rail ends are subject to.

### Southern Railway

Transverse and compound fissures occurring in all rail of 1929 rolling prior to January 1, 1933, show a rate of 7.02 per 1000 tons for intermediate manganese against 0.32 per 1000 tons for carbon rail. The record of all failures in the same rail show a rate to January 1, 1933, of 31.0 per 1000 tons of intermediate manganese rail against 0.88 per 1000 tons of carbon rail.

Question 8—Report special tests or investigations on failed or defective intermediate manganese rails, and conclusions derived therefrom.

A.T. & S.F.—Investigation not yet completed.

New York Central—Any investigations which we have made recently on defective medium manganese rails show the same results as previously reported, that is, high physical properties, general freedom from segregation, and finer grain structure than is obtained usually in standard open hearth rails.

Question 9—What conclusions, briefly stated, have you arrived at as to the relative merits of intermediate manganese compared to standard open hearth rails.

A.T. & S.F.—See Question 4.

Boston & Maine—We do not plan to purchase any more medium manganese rails due to the fact that our records indicate that medium manganese rails develop batter at a more rapid rate than carbon steel rails and the further fact that we have had a large number of split head rails due to segregation.

Illinois Central—See Question 4.

Canadian National & Kansas City Southern—No conclusions have been made as yet.

Missouri Kansas Texas—See Question 4.

Northern Pacific—We do not believe that the very slight if any improvement in wearing qualities and resistance to batter in the intermediate manganese rail would compensate for the large increase in horizontal split heads. It is possible, however, that revised specifications for manganese and carbon might so reduce the appearance of horizontal split heads that this objection would be overcome.

New York Central—Medium manganese rails have invariably shown better properties and structural condition than standard open hearth rails, but the steel as commercially handled at the present and in the past has been prone to shattering which has developed considerable number of head failures of the horizontal crushed or split type.

Southern—We very much prefer open-hearth rail to intermediate manganese rail.

## Heat Treated Steel Rails

## QUESTIONNAIRE ON HEAT TREATED RAILS

1. Rails purchased during 1932 and 1933 not previously reported, giving following details:—

| COMPANY | PLANT | NO. RAILS | LENGTH | ROLLED | WEIGHT | SECTION |
|---------|-------|-----------|--------|--------|--------|---------|
|---------|-------|-----------|--------|--------|--------|---------|

2. Report results of special tests on new rails, comparing treated versus untreated.

3. Present contours or tabulated results of investigations on wear of rail heads, comparing treated and untreated rails, giving details of curvature, tonnage, age of rail, etc.

4. Present general or specific data on batter and chipping of rail ends, comparing treated and untreated rails.

5. Itemized list of any rail failures.

6. Report results of investigations on any failed heat treated rails.

7. What conclusions, briefly stated, have you arrived at of the relative merits of treated compared to untreated rails?

The purchase of heat treated rail during 1932 and 1933 were very light. They consisted of 300 tons of 100 lb. A.R.A.-B rail in 1932, a like amount in 1933 by the Interborough Rapid Transit Company of New York and 120 tons by the New York Rapid Transit Company in 1932 from the Bethlehem Steel Company and 160.6 tons of 130 lb. rail by the Norfolk & Western in 1932 and 161.1 tons of 130 lb. rail by the Erie Railroad in 1933, from Carnegie Steel Company. The Bethlehem rail was made by their so called "Lead Bath" process and the Carnegie rail by the "controlled cooling" process.

The following data was received in reply to the questionnaire:

## Boston &amp; Maine

| Location                          | Buckland, Mass. | Hoosick Falls, N.Y. |

| High Rail                         | 51 per cent     | 85 per cent         |
| Low Rail                          | 51 per cent     | 69 per cent         |

No rail failures reported. Our experience thus far has indicated that heat treated rail is giving us much better service than ordinary carbon rail. Our tests, however, have not been conducted long enough to permit definite recommendation. Our experience in the use of heat treated rail in crossing frogs indicates a marked superiority over solid manganese.

| Rail Failures—No failures                                      |                     |                   |

## Conclusions

The heat treated rails, due to increased toughness, are abraded to a lesser extent than the untreated, the ratio being 1. to 1.78.

The batter both in length and intensity at the rail ends is slightly greater on the untreated rails.

## The Chesapeake and Ohio Railway Company

QUESTIONNAIRE ON HEAT TREATED RAIL—BETHLEHEM  
"LEAD BATH" PROCESS

1. Rails purchased during 1932 and 1933 not previously reported, giving following details:\*

A small portion of this rail was purchased during 1930 and the balance in 1931, making a total of 1000 tons.

2. Report results of special tests on new rails, comparing treated versus untreated.

A—This rail has been laid at two locations, approximately 500 tons at each point. The first location is on the Marion District, Westbound track M.P. 32.11 to 36.49, laid January 1932. A small portion is on a curve at the east end but by far the largest part is on a tangent. The rail has shown very little wear at this point after 21 months of service under heavy coal traffic. The batter has been so small that it is hardly possible to measure.

The other 500 tons was laid on the Rivanna District, M.P. 102.17 to 104.88, during August 1931 and August 1932. The east end of this rail was laid alternately with common open hearth rail. This method was followed in order to obtain a direct comparison of the two types of rail.

General Condition of Test Rails: The common O.H. rail on the tangent test track was in good condition but on the curved track the ends of the rail were of a poor appearance, some chipped, some ragged or frayed at the end of the running surface. Almost without exception the Heat Treated rail was in fine condition and to the eye most of the rail ends were clean and new in appearance. The column "Percent Chipped" in attached table does not tell the whole story for where many of the common rails had large prominent chips, chipping on the Heat Treated rails was of a minor nature, there being no really noticeable chipped rail ends.

3. Present contours or tabulated results of investigations on wear of rail heads, comparing treated and untreated rails, giving details of curvature, tonnage, age of rail, etc.

A—This information included in table presented under question 4.

4. Present general or specific data on batter and chipping of rail ends, comparing treated and untreated rails.

A—A record of measurements was made on the test rails and of general information bearing on the study. The following points are explanatory and an extension of information obtained.

| Description of Location                                       | Group Number                | No. of Joints Still in Test 10-4-33 | No. of Jts. \* One less joint included in Average Batter on Leaving Rail  
 \*\* One more joint included in Average Batter on Receiving "

NOTE: Track under test has traffic in both directions but E.S. traffic is approximately three times W.S. therefore the west rail of joint is considered the leaving end and the east rail receiving. Built up joints are omitted from test data.

1. The grouping (1-a, 1-b, 2-a, etc.), was intended for comparing the two types of rails on tangents, on high side of curves, and on low side of curves. Possibly the 3 and 4 groups do not contain sufficient number of rails for a conclusive test at their particular location. More will develop as the study continues.

2. Of 57 common rails laid in March 1931, fourteen battered and chipped to such an extent that they had to be built up by welding. These welded joints constitute 24.6 per cent of the original total of groups 1-b, 2-b and 4-b. As of October 4, 1933, none of the heat treated rail had been rebuilt, and none needed to be rebuilt, but even though almost a fourth of the common rail had already been rebuilt there were several more of the same rail battered and chipped sufficient to need welding.

3. End flow is interesting as a matter of record but actually it is not of great importance in a study of this type. It is probably very much dependent on such extraneous factors as the amount of uniformity there is in joint bolt tightness and the snugness of rail anchors. For instance suppose there is play enough between anchors and ties to allow the expansion of three rails to be taken care of at one joint and assume that two sets of joint bars are tightly bolted and one not near so tight. Then all the expansion will be released at the loose joint, the flowed lip at that joint will be mashed or broken off, and the other two joints undisturbed.

#### 5. Itemized List of Rail Failures.

\* Rails marked thus were found by Sperry Car.

Rail 86344—C—13 failed after two weeks service in track.

Rails 83348—D—9, 83350—D—14 and 86361—D—10, failed on February 12th, 16th and 29th, 1932, respectively. This rail was laid during the first and second weeks of January 1932.

#### 6. Report results of investigations on any failed heat treated rails.

A—The 11 rails found by Sperry car in 1932 and the three rails mentioned in the latter part of paragraph five were studied and the following report submitted:

The rails were put through the roller tests at  $\frac{5}{8}$ " deflection in 60 inches which ruptured all rails but 83348—G—3 and 83350—E—11.

An unusual feature of these ruptures is their size; in most cases the greater part of the head was ruptured, and the appearance convinced us that this had happened before the rails were annealed. While these ruptures are extremely large in size, we have not been able to find any trace of shatter cracks in any of these rails, although search was made by hot acid etching twice the usual amount of mid section of the head.

Brinell hardness determinations at various parts of the section show somewhat greater hardness than we usually get from this rail section. (The diagrams accompany-

ing the original report have been omitted. They show the following Brinell hardness limits:

In two rails, heat 83350, Brinell minimum 293, Maximum 402  
 In four rails, heat 86361, Brinell minimum 311, Maximum 430  
 In seven rails, heat 83348, Brinell minimum 340, Maximum 418

A thorough investigation of the open hearth history convinces us that the steel quality is not responsible. We have the impression that the quench may have been more severe than usual. This might result from colder water or a delayed quench. If the rails were delayed in getting into the water, the standard time of quenching might cool the rail into the blue brittle temperature. We are working on means to guard against this in the future.

Rail 86344—C—13 was also studied and the following report submitted:

The broken rail has been received and examined with following results:

Rail was C-13 from heat 86L344 rolled in Nov. 1931.

Analyses of ladle and rail show—

|             | <i>C</i> | <i>Mn</i> | <i>P</i> | <i>S</i> | <i>Si</i> |
|-------------|----------|-----------|----------|----------|-----------|
| Ladle ..... | .750     | .74       | 0.21     | 0.29     | .18       |
| O.....      | .780     | .74       | .024     |          |           |
| Rail M..... | .783     | .74       | .027     |          |           |

Rail was broken about 6 ft. from end and the long piece was put through the roller bending machine with no other breakage. The rail was then beheaded and the head sent to the frog shop where it was bent in a hydraulic machine with no failures resulting. This was a most searching test, the rail head being bent to 45° in some of the thrusts of the ram without breaking and it was necessary to reverse the bend in order to obtain a fracture. All the fractures were clear and no evidence of heat cracks were found.

A cross section of the rail head adjoining the track break was polished and readings with Rockwell and Brinell hardness machines taken. The Brinell hardness varied between 351 and 387 and the Rockwell hardness, Scale C, between 33 and 42.

A cross section of rail head immediately back of the track break was given a hot acid deep etch which disclosed a slight sponginess in the upper center of the web; the head was fairly free from segregation and inclusions.

A close examination of the broken faces of the rail gave no clue as to the actual cause of failure. There were no indications of quenching cracks nor were the familiar features of transverse fissures to be seen, in fact, we inclined to the belief that the break started in the base, due to the appearance of the fracture in that location, but as no sign of a seam could be discovered the theory was impotent.

7. What conclusions, briefly stated, have you arrived at of the relative merits of treated compared to untreated rails?

A—It is believed that this rail has not been in track long enough for a definite conclusion to be found regarding its serviceability.

#### Interborough Rapid Transit Company (N.Y.)

During 1932 we purchased 300 tons of 100-lb. ARA-B section heat treated rails, 33' long, from the Bethlehem Steel Company. They were rolled at that company's Steelton plant during February.

We purchased from the same company during 1933, 300 tons of 100-lb. ARA-B section heat treated rails, 33' long. This rail was rolled at that company's Steelton plant during June. The rail is laid on curves of 200' to 800' radius.

Service records consistently show that the ratio of wear of heat treated rail in our specification carbon (.78 to .93) open hearth steel rail is approximately 0.50.

No heat treated rails furnished during 1932 and 1933 have failed to date.

#### Lehigh Valley Railroad

In regard to heat treated rails, I would advise that we have not purchased any heat treated rails on this railroad, but were given fifty (50) in connection with our regular rail purchases by Bethlehem Steel Company from their Steelton Plant, in 1928,

these rails being 39 ft. long, 136 lb. per yard. These rails were placed in track in October 1928, 25 being installed on a 13 degree curve and the remaining 25 on a 10 degree curve. Comparative measurements were made from time to time with the high carbon rail in the same curve, the latter rail running about .84 carbon. In November 1929 the rails on both curves were transposed on account of lateral wear on the high rail, and from observation and also measurements, very little difference could be noticed as between the heat treated and the high carbon rail. Furthermore, I could see no great difference in the batter or chipping of the ends. We had no rail failures.

In my opinion from our experience with the heat treated rail furnished in 1928, I do not believe it gives sufficiently better results to warrant the additional price, which I understand is approximately \$20.00 per gross ton in excess of the regular rail price.

#### New York Central Lines

1. No purchases in 1932 and 1933, excepting a lot of 82 rails of the 127 lb. Dudley section, which comprises normalized, box cooled, and rails of standard treatment for comparison. These have only recently been laid in service.

2. The above mentioned rails were rolled by the Illinois Steel—Gary Works in December 1932 and June 1933 and are all 39 ft. long.

3. On previously reported heat treated rails, the general observation shows that there is only slight superiority on the high side, and a very marked superiority on the low side of curves for heat treated rails over those untreated, in comparative test locations.

4. No noticeable difference in chipping. As to batter, the heat treated rails on the low side of curves are very markedly less battered than the untreated rails.

5. No rail failures have occurred, excepting the two previously reported in the 115 lb. Dudley treated rails on the P. & L.E. shortly after installation.

6. No reports on failed treated rails.

7. The only point of difference or superiority for the heat treated rails so far is found in the lesser flow of the low rails on curves, coupled with lesser batter on these rails.

#### Appendix J

### (8) REDESIGN RAIL SECTIONS HEAVIER THAN 100 LB. PER YARD SO AS TO OBTAIN THE MOST ECONOMICAL DISTRIBUTION OF METAL WITH THE MAXIMUM STRENGTH OF SECTION

G. W. Harris, Chairman, Sub-Committee; J. E. Armstrong, W. C. Barnes, A. F. Blaess, N. J. Boughton, C. T. Dike, J. M. Farrin, L. C. Fritch, C. R. Harding, W. H. Kirkbride, H. C. Mann, W. H. Penfield, W. H. Petersen, A. N. Reece, R. T. Scholes, J. R. Watt, Louis Yager.

As demand was made for the early adoption of a revised rail section whose weight would lie between that of the 131-lb. RE section adopted at the 1933 Convention and the present standard 100-lb. RE section, a section weighing 112-lb. per yard was developed and recommended by the Rail Committee for adoption as standard in place of the 110-lb. RE section.

Action on the Committee's recommendation could not be delayed until the following Convention and it was therefore submitted to the Association by letter-ballot dated July 1, 1933, and the recommendations were approved by a large majority vote. As a matter of record the form of the letter-ballot and result of the vote are given below.

This report is submitted as information.

AMERICAN RAILWAY ENGINEERING ASSOCIATION  
LETTER-BALLOT ON 112-LB. RE RAIL SECTION

Chicago, July 1, 1933.

TO THE MEMBERS:

Since the Annual Meeting in March, the Committee on Rail has been engaged on a revision of the 110-lb. RE Rail Section, shown on page 143 of the 1929 Manual.

A revised section was presented and approved at a recent meeting of the Committee on Rail. On following pages the general principles governing the design and the properties of the new 112-lb. RE Rail Section; argument in support of the recommendation for its approval, and an illustration of the revised section, are set forth.

In order that Railway Companies may have the benefit of the new standard and place rail orders therefor promptly, the Board of Direction has directed that the revised section be submitted to the membership for approval by letter-ballot.

In the event that a majority of the members voting approve the revised section, it will be presented to the Board of Directors of the American Railway Association for endorsement and approval.

Please indicate your vote on attached coupon and return it to the Secretary's office not later than July 29, 1933.

E. H. FRITCH, *Secretary*.

ARGUMENT TO ACCOMPANY LETTER-BALLOT ON ADOPTION OF  
112-LB. RE RAIL SECTION

Following the action taken at the March, 1933, Convention of the Association, in approving the 131-lb. RE Rail Section, the Committee on Rail has had under consideration a revision of the 110-lb. RE Rail Section. At a meeting held on June 15, 1933, the Committee agreed upon a rail section weighing 112.4 lb. per yard, to be substituted for the 110-lb. RE Rail Section now in the Manual.

It is desired to promptly submit this new 112-lb. section, with the 131-lb. section already adopted by the Association, to the American Railway Association for endorsement and approval and presentation to the member railroads, so that the new sections may be available for rolling the latter part of this year.

To this end the recommendations of the Committee on Rail are submitted herewith to the Association for adoption by letter-ballot.

In designing this new section, no change was made in the width and thickness of base, as compared with the 110-lb. section, so as not to affect the interchangeability of tie-plates, rail anchors, and the preboring of ties. No change was made in the width of head at the gage line at  $\frac{5}{8}$ -inch below the top of the head.

Reference is made to Fig. 1, on a following page, showing this section. A comparison of its properties with the present 110-lb. RE section follows:

|                                     | 110-lb. RE | 112-lb. RE |
|-------------------------------------|------------|------------|
| Stiffness (M. I.).....              | 100.0%     | 115.5%     |
| Strength (Sec. Mod.).....           | 100.0%     | 108.1%     |
| Weight or Area.....                 | 100.0%     | 101.8%     |
| Area of Head (Total Area 100%)..... | 37.4%      | 35.9%      |
| Area of Web (Total Area 100%).....  | 23.0%      | 25.1%      |
| Area of Base (Total Area 100%)..... | 39.6%      | 39.0%      |
| Ratio M. I. to Area.....            | 5.27       | 5.97       |
| Ratio Sec. Mod. to Area.....        | 1.55       | 1.64       |
| Ratio Base to Height.....           | .88        | .83        |

These desirable increases of the 112-lb. section are secured with comparatively small increase in weight over the present 110-lb. section. It is intended that this new section will be the only section between the 100-lb. RE and the 131-lb. RE sections, and therefore its weight might properly approach the half-way point. Consideration, however, was given to the desire of the users of the present 110-lb. RE section not to increase the weight to any great extent. Within reason, the weight was permitted to fall where it would, as the result of the rail dimensions agreed upon.

The distribution of the metal of the head, web and base for this section falls between that of the present 110-lb. RE section and that of the 131-lb. RE section, both of which have been successfully rolled by the manufacturers.

The betterment of the joint bars is one of the most important considerations and ranks with the improvement of the rail section itself. Any increase in the fishing depth of the rail increases the stiffness and strength of the joint bars. There is not much opportunity to secure these increases by widening the joint bars.

A comparison of a joint bar for the 112-lb. section with a similar type for the present 110-lb. RE section follows:

|                              | 110-lb. RE | 112-lb. RE |
|------------------------------|------------|------------|
| Stiffness (M. I.).....       | 100.0%     | 135.0%     |
| Strength (Sec. Mod.).....    | 100.0%     | 122.6%     |
| Weight .....                 | 100.0%     | 108.7%     |
| Ratio M. I. to Area.....     | 1.76       | 2.19       |
| Ratio Sec. Mod. to Area..... | .81        | .91        |

This indicates a worth-while betterment of the joint bar itself.

In addition to the recommended new rail section, there are several details incident thereto included in the ballot, such as the withdrawal from the Manual of the present 110-lb. RE Rail Section, revisions of the Table of Rail Drillings to Standard Rail Sections, and the revisions of paragraphs 3 and 4 on page 162 of the 1929 Manual, specifying the diameters of the bolts and the bolt holes in the rail. These two paragraphs are revised to conform to the new sections and also to increase the diameters of the bolt holes  $\frac{1}{8}$ -inch. The present adopted diameters of bolt holes in the rail are only  $\frac{1}{8}$ -inch larger than the diameters of the bolts, which is insufficient to provide proper clearance for expansion or the admission of the bolts without probable damage to the threads. The proposed revisions conform closely to current practices on the majority of the roads.

The trend of the times is towards standardization and simplified practice, for which there is a strong demand in the interests of economy. It is the purpose of the Association to recommend standards that roads will use; the object being to eliminate the multiplicity of standards, for which railroads have been criticised.

In the revisions of the rail sections, the Committee on Rail has sought to present designs giving maximum utility for the weight of metal. The 131-lb. section has already been adopted. The Committee recommends the proposed 112-lb. section for your favorable consideration.

## RECOMMENDATIONS SUBMITTED FOR APPROVAL

1. Withdrawal from the Manual of the present 110-lb. RE Rail Section, shown on page 143 of the 1929 Manual.
2. Adoption and publication in the Manual, as the standard 112-lb. RE section, of the rail section shown as Fig. 1.
3. Revision of the table headed "Application of Recommended Rail Drilling to Standard Rail Sections," page 162 of the 1929 Manual, by eliminating all reference to 110-lb. RE Rail Section and Drilling.
4. Addition to the table referred to in Recommendation 3, of "112" in first column; "RE" in second column, and "3 13/16-inch" in third column.
5. Revision of paragraph 3, page 162 of the 1929 Manual, to read as follows: "For standard rails up to and including 112-lb. per yard, one-inch bolts and 1 1/8-inch bolt holes should be used."
6. Revision of paragraph 4, page 162 of the 1929 Manual, to read as follows: "For standard 131-lb. per yard rail, 1 1/8-inch bolts and 1 1/4-inch bolt holes should be used."

(10) DESIGN JOINT BARS FOR RE RAIL SECTIONS  
AS DEVELOPED

G. W. Harris, Chairman, Sub-Committee; J. E. Armstrong, W. C. Barnes, A. F. Blaess, N. J. Boughton, C. T. Dike, J. M. Farrin, L. C. Fritch, C. R. Harding, W. H. Kirkbride, H. C. Mann, W. H. Penfield, W. H. Petersen, A. N. Reece, R. T. Scholes, J. R. Watt, Louis Yager.

This subject was added to the Committee assignments during the fiscal year with request for early completion. After intensive study your Sub-Committee designed a joint bar section and assembly for use with the 112-lb. RE rail which the Committee recommends for adoption as standard. As there was need of early action, the Committee's recommendations were submitted to the Association by letter-ballot on January 20, 1934, but the result of this letter-ballot is unknown at the date of this writing.

As a matter of record the form of the letter-ballot of January 20, 1934, referred to is given below.

This report is submitted as information.

## LETTER-BALLOT

on

## AREA JOINT BAR AND ASSEMBLY FOR 112-LB. RE RAIL

Chicago, January 20, 1934.

## TO THE MEMBERS:

At the March 1933 Convention, the Association adopted the 131-lb. RE Rail Section, and since the Convention the 112-lb. RE Rail Section was adopted by letter-ballot dated July 1, 1933.

These sections have been generally adopted for use by those roads that have been using the 130-lb. and 110-lb. RE sections.

The Association has never recommended standard joint bar sections for the several weights of rail. The matter has been left to the determination of each individual road. As a result there is a large number of different types and sections of joint bars, different sizes of bolts and different sizes and spacing of bolt holes in the joint bars and rails.

With the adoption of the new rail sections, it seems appropriate that standard joint bar sections and assemblies be recommended for those sections. At the suggestion of the President of the American Railway Association the subject was assigned to the Rail Committee, to recommend rail joints for the 112-lb. and the 131-lb. RE rail sections.

Plan of the Joint Bar and Assembly for the 112-lb. RE rail is submitted herewith. The plan includes the joint bar section, the bar punching, the rail drilling and the bolt. The Rail Committee recommends this section and assembly to the Association for adoption as standards and for publication in the Manual.

In the event that a majority of the members voting approve the Joint Bar and Assembly for 112-lb. RE rail, it will be presented to the Board of Directors of the American Railway Association for endorsement and approval.

Please indicate your vote on attached coupon and return it to the Secretary's office not later than February 15, 1934.

E. H. FRITCH, *Secretary*.

## RECOMMENDATIONS SUBMITTED FOR APPROVAL

1. Adoption and publication in the Manual of the 112-lb. Joint Bar section.
2. Revision of the Revision of paragraph 3, page 162, 1929 Manual, made in Proposal No. 5 Letter-Ballot on 112-lb. RE rail section, July 1, 1933, to read: "For standard rails up to and including 131-lb. per yard, one-inch thread diameter bolts and  $1\frac{1}{8}$ -inch bolt holes should be used."
3. Elimination of Revision of paragraph 4, page 162, 1929 Manual, made in Proposal No. 6 Letter-Ballot on 112-lb. RE rail section, July 1, 1933, which reads: "For standard 131-lb. per yard rail,  $1\frac{1}{8}$ -inch bolts and  $1\frac{1}{4}$ -inch bolt holes should be used."
4. Revision of Proposal No. 4 Letter-Ballot on 112-lb. RE rail section, to read: "112" in first column; "R.E." in second column; " $2\frac{7}{8}$ -inch" in third column.
5. Adoption and publication in the Manual of the 24-inch and the 36-inch joint bar bolt hole punching.
6. Adoption of the rail drilling for the 112-lb. RE rail section.
7. Revision of the Standard Track Bolts and Nuts, as given in Supplement to Manual of 1929, Bulletin 327, page 13, Column—"Length Under Head," to read: "From 3 to 7 inches by steps of  $\frac{1}{4}$ -inch," and "From 7 to 10 inches by steps of  $\frac{1}{2}$ -inch." Bulletin 327—page 17, to be revised to cover a recess of  $\frac{1}{4}$ -inch and thickness of recessed nut of  $1\frac{3}{4}$ -inch for one-inch diameter bolt.

## RECOMMENDATIONS SUBMITTED FOR APPROVAL

## SUPPLEMENT TO REPORT OF COMMITTEE IV—RAIL

(Bulletin No. 363, Page 829, Vol. 35—January, 1934)

---

*To the American Railway Engineering Association:*

Your Committee presents herewith its report on the design of joint bar and assembly for the 131-lb. RE rail.

At the March, 1933, Convention, the Association adopted the 131-lb. RE Rail Section, and since that Convention the 112-lb. RE Section has been adopted by letter-ballot, dated July 1, 1933.

These sections have been generally adopted for use by those railroads that have been using the 130-lb. and the 110-lb. RE sections.

The Association has never adopted standard joint bar sections for the several weights of rail. The matter has been left to the determination of each individual road. As a result there is a large number of different types and sections of joint bars, different sizes of bolts and different sizes and spacing of bolt holes in the joint bars and rails.

With the adoption of the new rail sections, it seems appropriate that standard joint bar sections and assemblies be adopted for these rail sections. At the suggestion of the President of the American Railway Association, the subject of recommending joint bars for the 112-lb. and the 131-lb. RE rail sections was assigned to this Committee.

The Joint Bar and Assembly for the 112-lb. rail was completed and approved by the Committee on January 4, 1934. As early action by the Association was urgent, on account of the desire of several roads to use the bar, if adopted, with rails for which orders were pending, a letter-ballot was sent out to the members of the Association on January 20, 1934. The result of this ballot was for the adoption of the joint bar and assembly by a vote of 444 to 160.

A plan for a Joint Bar and Assembly for the 131-lb. RE rail is submitted herewith. This joint bar section was designed by Dr. A. N. Talbot, Chairman of the Committee on Stresses in Railroad Track, collaborating with the Sub-Committee having in charge the design of the 131-lb. joint bar.

Stimson,  
1. Michel,  
see, J. B.

RE rail

the 131-lb.

*irman.*

This Sub-Committee was composed of the following members: E. Stimson, Chairman; W. J. Backes, C. B. Bronson, R. Faries, C. W. Johns, Wm. Michel, John V. Neubert, E. E. Oviatt, G. A. Phillips, G. J. Ray, W. P. Wiltsee, J. B. Young.

Recommendations for Adoption and Publication in the Manual:

1. Adopt the 131-lb. RE Joint Bar Section.
2. Change "Height of bolt hole above base of rail" for the 131-lb. RE rail section, adopted by the Association in 1933 from  $3\frac{1}{4}$  inches to  $3\frac{3}{32}$  inches.
3. Adopt the 24-inch and the 36-inch joint bar bolt hole punching.
4. Adopt the rail drilling for the 131-lb. RE rail section.
5. Adopt as a whole the plan of the "Joint Bar and Assembly for the 131-lb. RE Rail," submitted herewith.

Respectfully submitted,

THE COMMITTEE ON RAIL,

EARL STIMSON, *Chairman*.

Chicago, March 5, 1934.

## REPORT OF COMMITTEE XXI—ECONOMICS OF RAILWAY OPERATION

J. E. TEAL, *Chairman*;  
B. T. ANDERSON,  
R. C. BARDWELL,  
G. S. CRITES,  
H. C. CROWELL,

JOHN WORLEY,  
*Committee.*

*To the American Railway Engineering Association:*

Your Committee respectfully presents report covering the following subjects:

1. Revision of Manual, including revision of the method for the determination of proper allowances for maintenance-of-way expenses due to increased use and increased investment.

Report under this assignment is presented as Appendix A, and it is recommended that the last paragraph be adopted for publication in the Manual.

3. Methods or formulae for the solution of special problems relating to more economical and efficient railway operation.

Report under this assignment is presented as Appendix B, and it is recommended that it be received as information.

5. Methods for determining most economical train length, considering all factors entering into transportation costs, collaborating with Operating Division.

Report under this assignment is presented as Appendix C, and it is recommended that it be received as information.

6. Effect of volume of traffic on railway operating expenses, collaborating with Committee XXII—Economics of Railway Labor.

Report under this assignment is presented as Appendix D, and it is recommended that it be received as information.

Progress is reported on the following subjects:

2. Methods for obtaining a more intensive use of existing railway facilities, with particular reference to securing increased carrying capacity:

- (a) Without material additional capital expenditures.
- (b) With due regard to reasonable increases in capital expenditures consistent with traffic requirements.

4. Most economical makeup of track to carry various traffic densities, collaborating with Committees I—Roadway, II—Ballast, III—Ties, IV—Rail, V—Track, and X—Signals and Interlocking.

7. Discontinuance of non-paying trains and agencies, rendered so by all forms of highway competition.

8. Operation with reduced number of main tracks.

Respectfully submitted,

THE COMMITTEE ON ECONOMICS OF RAILWAY OPERATION,

J. E. TEAL, *Chairman.*

### Appendix A

#### (1) REVISION OF MANUAL, INCLUDING REVISION OF THE METHOD FOR THE DETERMINATION OF PROPER ALLOWANCES FOR MAINTENANCE-OF-WAY EXPENSES DUE TO INCREASED USE AND INCREASED INVESTMENT

J. F. Pringle, Chairman, Sub-Committee; H. C. Crowell, S. W. Fairweather, J. M. Farrin, C. H. R. Howe, E. E. Kimball, M. F. Mannion, F. H. McGuigan, Jr., L. S. Rose, C. E. Smith, C. H. Stein, J. E. Teal.

The subject-matter pertaining to maintenance of way expenses now appearing in the Manual was adopted for publication at the Annual Convention in 1925. Since that time there have been changes in maintenance of way practices which have led to the suggestion that the figures shown on page 1430 of the Manual of 1929, under Column 4, "Per cent affected by use," should be revised to conform to current practices.

The figures appearing in the Manual are not intended to be final, but, as stated in the Manual on page 1430, "These percentages may be varied to suit the circumstances of each particular problem."

After carefully reviewing the figures, your Committee are of the opinion that there has not been sufficient change in maintenance of way practices or sufficient further information developed to warrant any changes, especially in view of the wording of the text above quoted.

Your Committee have found, however, that the method has been used under conditions and for purposes contrary to the original intention, which has led to erroneous deductions, and therefore recommend that the following cautionary paragraph be included in the Manual on page 1432, after the first paragraph at top of page:

"Care should be exercised in selecting the period to be used as the base period for comparisons. The total equivalent gross ton miles in the base period should be the normal equivalent gross ton miles, that is, the normal use for which the property is maintained. The base period should extend over a sufficient period, with normal conditions, in order that the maintenance expenditures during the period will be normal. Comparisons of one year with another cannot be made under this method, unless the equivalent gross ton miles and maintenance expenditures for the year used as the base period are the normal equivalent gross ton miles and normal expenditures for the property."

### Appendix B

#### (3) METHODS OR FORMULAE FOR THE SOLUTION OF SPECIAL PROBLEMS RELATING TO MORE ECONOMICAL AND EFFICIENT RAILWAY OPERATION

C. H. R. Howe, Chairman, Sub-Committee; W. N. DeRamus, F. H. McGuigan, Jr., J. A. Parant, E. S. Pennebaker, J. E. Saunders, H. W. Snyder

#### ECONOMIC EFFECT OF THE 131-LB. R.E. SECTION RAIL ON THE COST OF OPERATION AS COMPARED WITH THE 130-LB. R.E. SECTION

The adoption of a new standard 131-R.E. rail section by the American Railway Engineering Association at its March, 1933, convention, raises the question as to what economies in the cost of operation, if any, would be gained by replacing the 130-lb. R.E. rail with the 131-lb. R.E. section.

The objective sought in the change of sections is greater girder strength and improved texture without undue sacrifice of lateral strength or other attributes of value

in the 130-lb. R.E. section. If this is accomplished, the result should be longer life of the rail.

The purpose of this analysis is to determine whether or not an improvement has been secured. The economic comparison which follows has been greatly simplified by following, in a large measure, the methods employed by A. N. Reece, Chief Engineer of the Kansas City Southern Railway, which were published as a monograph in Vol. 31, A.R.E.A. Proceedings; the research work by James M. Farrin, Special Engineer of the Illinois Central Railroad in Track Combination Evaluation; the studies on the subject of Ties, by Dr. Hermann von Schrenk; and the data obtained from the experiments conducted by Prof. E. E. Schmidt, of the University of Illinois.

All the data used in connection with tonnage and costs of operation, maintenance of way and equipment are taken from the permanent records of a Class I railway, which will be designated in this report the North and South Railway.

### COMPARISON OF THE NEW 131-LB. R.E. AND THE OLD 130-LB. R.E. RAIL SECTIONS

The outstanding difference between the two sections is the increase in the moment of inertia of the 131-lb. R.E. rail, the 130-lb. R.E. having a moment of 77.4, the 131-lb. R.E. a moment of 89.0, this being an increase of 15.0 per cent. This increased moment is the result of decreasing the base area 0.20 sq. in., or 4.00 per cent, and adding the metal taken from the base and head plus an additional amount of 1.56 lb. per yard to the web to increase the height of the section by  $\frac{3}{8}$ -in. The area of the head remains approximately the same, the actual decrease being but 0.10 sq. in. but the design of the head is changed materially, the depth being decreased  $\frac{3}{8}$ -in. and the width increased  $\frac{1}{8}$ -in. The effect of this change in head design on cooling, texture and hardness will be discussed later under the topic Life of Rail.

Whereas the total lateral moment of inertia of the section has been slightly reduced, the lateral moment of inertia of the head has actually been increased from 2.8 to 3.0. This will effect not only a better distribution of stresses in the web but also reduce stresses in the head, as a part of these stresses are due to the lateral forces on the rail.

Comparison of the section moduli of the heads and bases of the two sections shows that the 131-lb. R.E. is better balanced than the 130-lb. R.E. This should produce more nearly equal stresses about the neutral axis of the rail in its action as a continuous girder, and should tend to reduce the effect of the stress in aggravating transverse fissure development and other defects in the rail head. The vertical sides of the head should improve the design and fit of switch points.

The principal change in the base is a reduction of  $\frac{1}{2}$ -in. in the thickness.

The change in the web design whereby the point of minimum thickness is raised from  $3\frac{3}{8}$ -in. to  $4\frac{1}{4}$ -in. above bottom of rail, is of material benefit, for notwithstanding the increased radius of the curve as it swings down there is more metal in the web, just above the base, than there is in the 130-lb. R.E. at this point. This increase in bulk should have the effect of slightly retarding the cooling of the base in rolling, thus modifying the after-rolling camber.

### Life of Rail

The controlling factor in the economics of the rail itself is the cost of service life obtained measured in gross tons traffic, specifically designated "Gross Ton Miles per Mile". There are many elements that affect the service life, and an attempt is made in this report to review those that are considered important.

### Effect of Wear on Life of Rail

At the present time wear due to the abrasion of the rail head is not a major cause of removal from main line track of the North and South Railway, either on tangent or curves. On the latter the extensive use of curve grease has largely disposed of this factor, and curve rails now remain in track until necessary to remove on account of batter, underhead wear, wheel burns and surface or line bending. Measurements of rail removed from main line track on the North and South Railway show the average depth of head wear to be  $\frac{3}{8}$ -in., which in itself is not sufficient cause for removal.

Much work is being done at the present time in an effort to decrease the number of rail removals on account of batter, such as heat treating, rebuilding by welding, bevelling rail ends and the use of improved rail joints. By these means the life of rail may be so extended that uniform wear may be an important consideration in determining its service life.

The depth of head of the 131-lb. R.E. is  $\frac{3}{8}$ -in. less than the old 130-lb. R.E. but it has approximately the same head area and is  $\frac{1}{16}$ -in. wider, which with its improved contour of wearing surface that more closely approximates that of wheel flanges and treads than the 130-lb. R.E., should produce more uniform cold rolling and reduce the rate of sideflow and wear.

### Effect of Carbon Content Upon the Life of Rail

Carbon content plays an important part in the life of rail, but it is assumed in the case of the two sections considered that the carbon content range is the same and this factor is disregarded.

### Effect of Amount of Rolling and Rapidity of Cooling Upon the Life of Rail

The two sections being of approximately the same weight it is evident that the amount of rolling or working will be the same, so that if we are to find an improvement in this respect it must be as a result of cooling. Application of the head area-perimeter ratio test as shown in Mr. Reece's Table IV indicates that the new section will be slightly harder and the rate of batter slower than the 130-lb. R.E., as shown by the following tabulation:

| <i>Rail<br/>Section</i> | <i>Area of<br/>Head<br/>(Sq. In.)</i> | <i>Perimeter<br/>(In.)</i> | <i>Area-<br/>Perime-<br/>ter Ratio</i> | <i>Relative<br/>Hardness</i> | <i>Relative<br/>Rate of<br/>Batter</i> |
|-------------------------|---------------------------------------|----------------------------|----------------------------------------|------------------------------|----------------------------------------|
| 85 K.C.S. ....          | 3.14                                  | 6.86                       | .458                                   | 100 per cent                 | 100 per cent                           |
| 130 R.E. ....           | 4.63                                  | 8.39                       | .552                                   | 83                           | 121                                    |
| 131 R.E. ....           | 4.53                                  | 8.37                       | .540                                   | 85                           | 118                                    |

### Effect of Stiffness of Rail Upon its Life

Joint bars are not as stiff as the rails they connect, therefore there is a break in the depression curve of the rail at the joint as the bars are effective only to the extent of producing a reduction of 80 per cent in the slope between the surface of the abutting rail ends. Based on this theoretical consideration it may be assumed that a reduction in rail batter is obtained equal to the reduction in slope between the rail surfaces. When Mr. Reece's Table V is examined, it will be noted that there is but 3 per cent difference between the Relative Slope and Rail Batter percentages of the 127-lb. rail section having a moment of inertia of 83.7 and the 150-lb. section with a moment of 121.1. From this it will be seen that the reduction in the batter of the 131-lb. R.E., section having a moment of 89.0, compared with a moment of 77.44 for the 130-lb. R.E. is about 1 per cent.

### Effect of Width of Head Upon the Life of Rail

It is reasonable to assume that the rate of batter will vary inversely in proportion to the width of surface exposed to batter. The 131-lb. R.E. head is 3-in. wide and the 130-lb. R.E.  $2\frac{1}{8}$ , an increase in width, or a batter decrease, of 2 per cent.

### Estimated Life of the Two Rail Sections

Summing up the effects of the factors that have been discussed, it is found, that with a life of 7.5 years with a gross ton miles traffic of 18.7 millions per year for the 130-lb. R.E., there will be an increase of 0.38 years for the 131-lb. R.E. section, as indicated below:

#### *Relative Batter in Per Cent Due to:*

| Rail<br>Section | Increased<br>Width<br>of<br>Head | Carbon<br>Content | Slower<br>Cooling<br>and Less<br>Rolling | Increase<br>in Rail<br>Stiffness | Combined<br>Effects | Relative<br>Life<br>Per Cent | Life in<br>Million<br>Gross Tons | Life<br>in<br>Years |

### Material Cost of the Two Rail Sections

There being so little difference in the life of the two rail sections, or in the type or size of fittings (excepting the joint bars which have not as yet been designed) and as the cost of laying will be the same in both cases, the cost of rail in place will be considered that of the actual tonnage less salvage value, plus the annual interest of the first cost of each section.

| Rail<br>Section | Cost<br>Per Ton | Salvage | Cost<br>Per Mile | Interest<br>@ 5 per cent | Labor<br>Renewing | Total<br>Cost<br>Per Mile | Million<br>G.T.M. | Cost Per<br>Million<br>G.T.M. |
|-----------------|-----------------|---------|------------------|--------------------------|-------------------|---------------------------|-------------------|-------------------------------|
| 130 R.E. ....   | \$40            | \$21    | \$3,871          | \$1,452                  | \$750             | \$6,073                   | 140,185           | \$43.32                       |
| 131 R.E. ....   | 40              | 21      | 3,917            | 1,543                    | 750               | 6,210                     | 147,194           | 42.19                         |

### Effect of Rail Upon Track Maintenance

In a study of this subject prepared by James M. Farrin, Special Engineer of the Illinois Central Railroad, and published in Vol. 28, A.R.E.A. Proceedings, there is presented a method by which various track makeups may be evaluated in terms of track labor hours. Numerous combinations of rail, ties, ballast and subgrade are shown by Mr. Farrin, but as in our present comparison all factors remain unchanged except rail section, we are concerned only with the effect that the change in rail stiffness will have upon the stiffness of the entire track structure, and consequently with the cost of maintenance.

The costs of maintenance shown by Mr. Farrin are the composite averages of a number of railways, but the determination of costs on any railway should be based on actual record of its own expenditures, and not on general payroll percentages. The North and South Railway records permit the use of actual cost figures in sufficient detail to enable us to make a reasonable estimate of the effect that the new 131-lb. R.E. section will have on the cost of maintenance.

During the year 1930 the labor cost on the 130-lb. rail territory was \$579, or 1399 man hours per mile of track, including all labor costs in connection with line and surfacing, ballasting, respacing, regaging and tightening bolts.

As the difference in maintenance costs is not great for the two sections that we are comparing, we may accept Mr. Farrin's values for comparative maintenance labor percentages for various rail sections as being reasonably correct. Plotting the percentages,

and moments of inertia for the respective sections, we obtain a curve from which we may determine the values of the 130-lb. R.E. and 131-lb. R.E. sections (see chart appended). These percentages may be interpolated in the percentages shown in Mr. Reece's Table X, at the same time substituting actual costs of the North and South Railway. Doing so we find a reduction in maintenance labor cost of \$3.00 per million gross ton miles per mile, as indicated by the table below:

| <i>Rail<br/>Section</i> | <i>Track<br/>Rating<br/>Per Cent</i> | <i>Labor<br/>per Mile<br/>per Year<br/>Man Hours</i> | <i>Comparative<br/>Maintenance<br/>Labor<br/>Per Cent</i> | <i>Cost of Labor<br/>per Mile per<br/>Million G.T.M.</i> | <i>Saving<br/>per Mile<br/>per Million<br/>G.T.M.</i> |
|-------------------------|--------------------------------------|------------------------------------------------------|-----------------------------------------------------------|----------------------------------------------------------|-------------------------------------------------------|

\* Correction has been made from Mr. Farrin's charts.

### Effect of Rail on Maintenance or Equipment

Wear and tear on equipment is affected by the condition of track, and the stiffness of the rail is an important factor in reducing the cost of locomotive and car repairs. In accordance with the A.R.E.A. Proceedings, Vol. 24, page 1060, 76.45 per cent of the costs chargeable to the above repairs will be affected by use of equipment. Quoting Mr. Reece: "The effect of use, or traffic, is damage from track condition, damage from train movement, and wear resulting from the production of energy." It is assumed that each of these causes equally affect the maintenance of equipment; then 25.48 per cent of the cost of the above repairs will be affected by track conditions. In 1930 the cost of such repairs was \$3,040 per mile, or \$93 per million gross ton miles, for the amount of the above accounts affected by track condition. The weighted average of the rail in North and South Railway main tracks in 1930 was 107.5-lb. per yard. On the above basis and having a cost of \$93 per million gross ton miles, the respective values for the 130-lb. R.E. and 131-lb. R.E. sections have been determined by plotting the values for track stiffness given in Mr. Reece's Table XII and interpolating the values for the 130-lb. R.E. and the 131-lb. R.E. based on moments of inertia.

From the tabulation below it is noted that the net saving of the 131-lb. R.E. over the 130-lb. R.E. is \$3 per Million Gross Ton Miles.

| <i>Rail Section</i>   | <i>Comparative<br/>Damage<br/>to Equipment<br/>from Track</i> | <i>1930<br/>Cost of Repairs<br/>Due to Track<br/>per Million<br/>G.T.M. of Traffic</i> | <i>Savings<br/>per Mile<br/>per Million<br/>G.T.M.</i> |

### Economies in Cost of Tie Renewals Per Mile of Main Track

Examination of the figures in Mr. Reece's Table XI shows that the savings effected by slight changes in rail sections are small. Even between the 127-lb. and the 150-lb.

sections the difference is but \$3 per Million Gross Ton Miles. The causes for tie removal due to mechanical wear as set forth in Dr. von Schrenk's monograph in A.R.E.A. Bulletin 306, and which Mr. Reece states in his paper amounted to 57 per cent on his railway for the year 1927, are accepted without serious question. Even neglecting the conditions of the general stiffness of track and accepting the moment of inertia ratio as a criterion, no serious discrepancy will occur in a comparison of the 130-lb. and 131-lb. R.E. sections.

During the year 1930 the tie renewals on North and South Railway 130-lb. territory averaged 169.7 per mile. As a number of those removed were untreated ties it is only fair to assume that had they all been treated the number of renewals would not have exceeded 160 per mile. Fifty-seven per cent of the 160 per mile renewed is 91 ties, and as the average cost of renewals in place was \$1.60 per tie, the cost per mile was \$146, or \$8 per Mile per Million Gross Tons Miles. A reduction based on an increase of fifteen per cent in rail stiffness would be approximately one dollar.

### Effect of Rail Upon Train Operation

Quoting Mr. Reece's article, "A decrease in train resistance effects a larger reduction in the cost of train operation than does a corresponding decrease in ruling grade, inasmuch as a heavier train can be handled not only on the ruling grade but also on all other grades with the same tractive effort and work as before. With rail offering less train resistance, the tonnage per train can be raised until the tractive effort is the same as previously, and a given amount of tonnage can be handled with fewer trains, less work and less cost." (Or if it is preferable, the original rating may be held but speed increased. Either change in operating method might be used to reduce train hours.)

The values for resistance shown in Mr. Reece's Table XV were calculated from the results of dynamometer car and other tests made on the Kansas City Southern Railway using 4.0 lb. per ton train resistance as basis. This figure being in accord with the experiments of Prof. E. E. Schmidt on "Freight Train Resistance," Bulletin 43, University of Illinois. The values for the 130-lb. R.E. and 131-lb. R.E. sections were found by plotting the reduction in resistance given in Table XV together with the respective moments of inertia, and interpolating the two R.E. sections.

| Rail<br>Section   | Reduction to<br>Resistance<br>Lbs. per Ton | Per Million Gross Ton Miles of Traffic               |                                                                  |                                         |     |                                             |                                                      |

During the year 1930 the gross ton mileage per mile of track on the 130-lb. rail territory of the North and South Railway was 18,691,319, and the freight train mileage per mile was 4651. The average tonnage per train was 4019 gross tons. The track mileage 1629.1. For purpose of comparison the 0.5 ruling grade is taken as a basis. With train resistance lowered, the tonnage rating can be raised, and the number of trains required to handle the same tonnage can be reduced.

As an adjustment of 12 tons would be impractical in the case of an individual train, the benefit, if any, of an increased tonnage rating must be derived from cumulative

results. It has been stated above that for the 130-lb. R.E. rail, 4651 trains averaging 4019 tons each were required to handle the 18,691,319 gross tons traffic. It being the practice, on the railway in question, to rate trains in terms of fifty-ton units, the average of 4019 tons is apparently the cumulative result of occasionally exceeding an established rating of 4000 tons. Expressing this in even unit tonnage we find that the 4019 average tonnage would ensue from handling:

|                               |
|-------------------------------|
| 2905 trains at 4000 tons each |
| 1746 " " 4050 " "             |
| 4651 trains                   |

The estimated increase in rating can be applied in the following manner. Adding the 12 tons to the 4019 tons average, and establishing a new rating of 4050 tons, the new average rating should be 4031 tons. This would result from handling:

|                               |
|-------------------------------|
| 2905 trains at 4050 tons each |
| 1732 " " 4000 " "             |
| 4637 trains                   |

From the table above it will be noted that on a 0.5 per cent ruling grade, 130-lb. R.E. rail, the resistance is 13.68-lb. per ton, and 4651 trains, rating at 4019 gross tons each, are required to handle the 18,691,319 gross tons per mile. The resistance of the 131-lb. R.E. rail is 13.64 lb. per ton, and with tractive effort remaining the same, the number of trains per mile and the gross tons per train are proportional to the resistance of the two rail sections.

The values for the 131-lb. R.E. section are:

$$\frac{18,691,319 \text{ G.T.M. per Mile} \times 13.64 \text{ lb. per Ton Resistance}}{4,019 \text{ G.T. per Train} \times 13.68 \text{ lb. per Ton Resistance}} = 4637 \text{ Train Miles per Mile}$$

and  $\frac{18,691,319 \text{ Gross Ton Miles per Mile}}{4,637 \text{ Train Miles per Mile}} = 4031 \text{ New Tonnage Rating}$

which is an increase of 12 gross tons.

The train miles per mile required for the 130-lb. R.E. rail is 4651 and for the 131-lb. R.E. rail 4637. The difference being 14 train miles per mile, the reduction per million gross ton miles is

$$\frac{14.0 \text{ Train Miles per Mile}}{18.7 \text{ Million G.T.M. per Mile}} = 0.8 \text{ Train Miles per Million G.T.M.}$$

Then as the cost per train mile is \$1.12 the saving will be  $\$1.12 \times 0.80$ , or \$0.90 per million gross ton miles per mile, as shown in the table.

The train mile costs are those given in the report to the Interstate Commerce Commission for 1930, and consist of 49 cents for wages of engine and train crews; 48 cents for lubricants, other supplies, locomotive repairs and engine house expense—of which 86 per cent, or 42 cents, was considered due to traffic; 19 cents for fuel; and 2 cents for water, a total of \$1.12 per train mile.

### Recapitulation

A summary of the factors entering into the economic value of the different rail sections per track mile follows:

| Rail Section                      | Saving in Track Labor | Saving in Tie Renewals | Saving in Maint. of Equipment | Saving in Train Operation | Total of Savings | Cost of Rail in Place | Net Savings |
|-----------------------------------|-----------------------|------------------------|-------------------------------|---------------------------|------------------|-----------------------|-------------|
| 131 R.E. ....                     | \$47.02               | \$1.00                 | \$28.80                       | \$7.39                    | \$84.21          | \$42.19               |             |
| 130 R.E. ....                     | 43.72                 | 0.00                   | 25.54                         | 6.50                      | 75.76            | 43.32                 |             |
| Saving 131 R.E. over 130 R.E. ... | \$ 3.30               | \$1.00                 | \$ 3.26                       | \$0.89                    | \$ 8.45          | \$ 1.13               | \$9.58      |

As the net saving per million gross tons per mile is \$9.58, the total saving per mile per year would be, based on 1930 tonnage,  $\$9.58 \times 18.7$  million G.T.M. per mile = \$179.15, and as there are 1629.1 miles of 130-lb. rail track the total saving would be  $\$179.15 \times 1629.1 = \$291,853$  per year. This total saving would not be wholly affected until all the 130-lb. R.E. rail now in track has been replaced by the 131-lb. R.E. The saving for 1933 new rail program would be 179 miles  $\times \$179.15$ , or \$32,068.00 of which 45 per cent would be for track labor and tie renewals. Future savings would be cumulative in line with such yearly programs as may be completed.

As stated at the outset, the preceding investigation of economics has followed the methods outlined in Mr. Reece's report. It has been given in detail, so as to bring out the essentials, but it should be considered that it is based on several assumptions, where actual data are not available. Other lines of investigation might appear to point to smaller savings, therefore the figures given above should be taken as indication that a general saving will be effected, rather than as a definite statement of the amount of reduced cost.

### Conclusions

The 131-lb. R.E. Section is an improvement over the 130-lb. R.E. Section for reasons as follows:

The increased girder strength of the 131-lb. R.E. section should produce better riding track, with less damage to equipment and track and a lower operating cost.

The improvement in the design of the rail head should result in better quality of metal, thus prolonging rail life and decreasing possibility of accidents due to breakage.

These factors should result in an appreciable saving without materially increasing investment.

### 130-LB. R.E. AND 131-LB. R.E. RAIL SECTION

FIG. 1

## Appendix C

## (5) METHODS FOR DETERMINING MOST ECONOMICAL TRAIN LENGTH, CONSIDERING ALL FACTORS ENTERING INTO TRANSPORTATION COSTS

L. S. Rose, Chairman, Sub-Committee; H. C. Crowell, G. D. Hughey, E. E. Kimball, J. A. Parant, H. F. Schryver, W. C. Sloan, H. W. Snyder, John Worley.

The Committee's report this year is in two parts—

(I) A supplement to the 1933 report on the capacity of steam locomotives.

(II) A preliminary comparison of freight train and yard switching performance for the purpose of noting the effect of operating heavy trains upon yard performance.

## (I) Supplementary Report on the Capacity of Steam Locomotives

Last year's report in connection with the Committee's assignment consisted of a study of the characteristics and performances of typical steam locomotives for the purpose of developing a simple method for determining the weight of train and the speed which will give the maximum gross ton miles per hour for various classes of locomotives and trains on various grades.

A number of tables covering a limited variety of locomotives were computed and a chart which was intended to be used for making adjustments in the tables was prepared. In applying the study to a number of problems a few errors have been discovered in the tables and some difficulty has been experienced in the use of the chart. For these reasons one of the objects of this supplement is to correct the errors, improve the chart and extend the tables to cover additional classes of locomotives.

Advantage is also taken of this opportunity to present a few examples to show how the data can be applied in the preliminary determination of locomotive capacities and other factors depending upon them. Some of the formulas in last year's report are repeated in order that all of the essential steps can be followed without the inconvenience of referring elsewhere.\*

The new master chart shown on the opposite page is arranged to give the weight on drivers in terms of the weight of engine and also in terms of the total weight of engine and tender for typical locomotives in order that adjustments can be made for various weights of tenders when using the tables which follow later.

EXAMPLE.—Find the adjustment required for the tender of the following locomotive:

|                                      |          |
|--------------------------------------|----------|
| Weight on drivers .....              | 122 tons |
| Weight of engine .....               | 182 tons |
| Weight of tender .....               | 140 tons |
| Total weight engine and tender ..... | 322 tons |

SOLUTION.—The ratio of the weight on drivers to the weight of engine is  $122/182$  or .67. Look for 67 per cent on the vertical scale, Fig. 1, and note that the weight on drivers for the corresponding typical locomotive amounts to 40.75 per cent of the total weight of engine and tender. Thus the weight of the typical locomotive including tender is  $122/.4075$  or approximately 300 tons. The weight of the tender for the typical locomotive is therefore 300 minus 182 or 118 tons against 140 tons for the given locomotive. Hence the adjustment for the excess weight of tender amounts to 22 tons, which must be deducted from the weight of trains obtained from the tables corresponding to the typical locomotive, as explained later.

\* See also the following articles and discussions: "Transactions of the American Society of Mechanical Engineers," July 30, 1933, Vol. 55, No. 9. "Report of R. A. Black, American Association of Railroad Superintendents," June, 1932. Baldwin Locomotive Company's Publication, 1932.

**CHART**  
**USED FOR OBTAINING H.P. CAPACITIES OF TYPICAL STEAM LOCOMOTIVES**  
**FROM THE WEIGHT OF ENGINE AND WEIGHT ON DRIVERS**

FIG. 1

A new feature of the master chart is the scheme adopted for showing the range covered by various classes of locomotives as indicated by the rectangles in the upper left-hand part of the chart. Thus it will be seen that the weight on drivers for the 4-6-4 type of locomotives as indicated by the rectangle 4-6-4 will range between 52.5 and 57.0 per cent of the weight of engine. Similarly the weight on drivers for the 4-6-2 type will range between 58.5 and 65.0 per cent of the weight of engine and so on for other classes of locomotives. The greater the number of drivers the greater will be the percentage of weight on drivers. The percentage of weight on drivers also increases for a given number of drivers when the number of leading or trailing axles is reduced.

The 2-6-0, 2-8-0 and 2-10-0 types are forerunners of the later types having one or more axles under the firebox and they are enough out of line to make it necessary to add the dotted line *ab* to the chart to cover this group.

In the case of switching locomotives the entire weight of the engine is on drivers, hence the 0-6-0, 0-8-0 and 0-10-0 types compose another group which are considered with their tenders in order to indicate the range covered by these types.

The horsepower curves at the bottom of the chart are the same as the ones shown in last year's report except that some of the lines have been extended to cover a wider field. Some liberties have been taken in the case of future designs of locomotives in the higher horsepower range as indicated by the thin lines between 35 and 40 h.p. per ton on drivers. Tests have shown horsepower capacities in excess of 40 h.p. per ton on drivers have been reached, but in order to make use of the high capacity it is necessary to have exceptionally good rail conditions so as to avoid slipping at high speed.

The following example will illustrate how the horsepower capacity of typical steam locomotives can be determined from the weight of engine and the weight on drivers:

EXAMPLE.—Find the cylinder and boiler capacities of the following locomotive:

|                                      |          |
|--------------------------------------|----------|
| Weight on drivers .....              | 122 tons |
| Weight of engine .....               | 182 tons |
| Weight of tender .....               | 140 tons |
| Total weight engine and tender ..... | 322 tons |

SOLUTION.—As described in the previous example, follow the horizontal line corresponding to 67 per cent (122/182) on the vertical scale to its intersection with the curve "Weight on Drivers", then the corresponding vertical line (40.75) to its intersections with the cylinder and boiler horsepower curves, then the corresponding horizontal lines to the vertical scale at the left and read 26.6 and 24.6 h.p. per ton on drivers for cylinder and boiler capacity, respectively.

The cylinder and boiler capacity of the typical locomotive will, therefore, be 26.6 and 24.6 times the weight on drivers (122 tons) or 3295 and 3000 h.p. respectively. The tables which are shown later will give the performance of the typical locomotive based on the horsepowers thus derived.

If the boiler pressure and diameter of pistons of the assumed locomotive are known, the cylinder horsepower of the locomotive can be computed by the following formulas based on Cole's ratios:

#### SIMPLE ENGINES USING SUPERHEATED STEAM

$$\begin{aligned}\text{Cyl. h.p.} &= .0229 \times P \times A \text{ for two-cylinder engines.} \\ &= .0343 \times P \times A \text{ for three-cylinder engines.} \\ &= .0458 \times P \times A \text{ for four-cylinder engines.}\end{aligned}$$

Where *A* = Area of one piston in square inches.  
and *P* = Boiler pressure in pounds per square inch.

The boiler horsepower of a locomotive is equal to the pounds of water it can evaporate per hour divided by the pounds of steam required to produce a horsepower hour (20.8-lb.).

In order to determine the amount of water the boiler is capable of evaporating it is necessary to know the square feet of heating surface in the firebox and in tubes and flues. It is customary to assume the firebox will evaporate 55 pounds of water per square foot of heating surface per hour and the tubes and flues 8 to 10-lb. per square foot per hour, depending upon their dimensions and spacing. For example, assume the locomotive has 350 sq. ft. of heating surface in the firebox and 4300 sq. ft. in tubes and flues, then the pounds of water evaporated would be computed as follows:

Pounds of steam from firebox surface  $55 \times 350 = 19,250$   
 Pounds of steam from tubes and flues  $10 \times 4300 = 43,000$   
 Total ..... 62,250  
 Boiler capacity equals  $62,250/20.8 = 2,990$  h.p.

On this basis the performance of the assumed locomotive will approximately equal the performance of the typical locomotive which can be obtained from the tables.

A - Without Booster

B - With Booster

Neglect weight on booster axle in all calculations)

$V_1 = .395 \times \text{h.p. per ton on drivers.}$

H.P. at Rim of Drivers =  $\frac{\text{Total T.E.} \times \text{M.P.H.}}{375}$

Example:

First Line T.E. "A" =  $500 \times 122 = 61,000$  "B" =  $600 \times 122 = 73,200$ .

Second Line M.P.H. =  $.395 \times 24.6 = 9.72$  T.E. "A" =  $480 \times 122 = 58,560$ .

"B" =  $70,760$  H.P. "A" =  $58,560 \times 9.72/375 = 1,519$  "B" =  $1,836$ .

Third Line M.P.H. =  $1.25 \times 9.72 = 12.15$  T.E. "A" =  $463 \times 122 = 56,486$ , etc.

If the heating surface were less than assumed or the tubes and flues could only evaporate 8 pounds of water per square foot of heating surface, then its performance would be less than that given in the tables and adjustments would have to be made as described later.

Usually the next step after the boiler capacity has been determined is to compute the speed-tractive effort and speed horsepower characteristics of the locomotive. The form given below shows a simple arrangement for calculating the output at the rim of the drivers allowing 20-lb. per ton on drivers for engine friction. These characteristics can be applied to speed-time-energy calculations over any profile.

Some methods for calculating speed-time-energy curves make separate allowances for weight on drivers, and non-driver weight and for the resistance of the train. No such allowances should be made when using the characteristics obtained as indicated by the form. The resistance of the locomotive in pounds per ton is assumed to be the same as for the train, since the engine friction has been allowed for in obtaining the tractive effort at the rim of the drivers.

The train resistance assumed for various classes of trains in computing the tables is given immediately following:

#### FREIGHT TRAIN RESISTANCE

(Pounds per Ton)

| Class              | Av. Wt.<br>Per Car | Miles per Hour |      |      |       |       |       |       |       |       |       |
|--------------------|--------------------|----------------|------|------|-------|-------|-------|-------|-------|-------|-------|

| Coal and Ore ..    | 80                 | 3.59           | 3.92 | 4.27 | 4.65  | 5.07  | 5.52  | 6.00  | 6.51  | 7.05  | 8.23  |
| Empty Cars ...     | 20                 | 8.56           | 9.12 | 9.79 | 10.60 | 11.53 | 12.58 | 13.75 | 15.06 | 16.48 | 19.69 |

The tables 1 to 9 inclusive on the following pages are for the purpose of showing the conditions which are necessary to obtain the maximum gross ton miles per hour and are the same as given in last year's report, except for a few corrections, but extended to cover locomotives having 50 and 60 per cent of their total weight on drivers. A set of tables covering future designs is also included.

In order to show the application of these tables a number of examples will be assumed:

EXAMPLE.—Assume the same locomotive as used in the previous examples and find the speed and weight of train which will give the maximum gross ton miles per hour on a .2 per cent grade based on the train resistance of manifest trains.

SOLUTION.—It has been shown that this locomotive corresponds to a typical locomotive having 40.75 per cent of its weight including tender on drivers. In the tables for manifest trains look for the group headed "Weight on Drivers" 40 per cent and opposite .2 per cent grade find the speed 29.6 m.p.h. and the weight of train 9.19 tons per ton of locomotive. As previously determined the weight of the typical locomotive is 300 tons hence the trailing weight which will produce the maximum gross ton miles per hour is  $300 \times 9.19$  or 2757 tons. On account of the excess weight of tender assumed it is necessary to deduct 22 tons from 2757 leaving 2735 tons, as the correct tonnage for the assumed locomotive. The gross ton miles per hour then become  $29.6 \times 2735$  or 80,956.

In this case it is an unnecessary refinement to correct for the difference between 40 and 40.75 per cent weight on drivers but in order to illustrate the principle the correct values of speed and train weight found by interpolation between the 40 and 45 per cent columns are 29.25 m.p.h. and 9.40 tons per ton of locomotive which gives  $(300 \times 9.40 \times 29.25)$  or 82,485 gross ton miles per hour for the typical locomotive and 81,842 for the assumed locomotive adjusted for excess weight of tender and for the difference in percentage of weight on drivers.

TABLE 1  
CONDITIONS FOR OBTAINING MAXIMUM GROSS TON MILES PER HOUR  
FOR VARIOUS CLASSES OF LOCOMOTIVES ON VARIOUS GRADES.

"TRAILING TONS "A" The tonnages shown in the "A" column are based upon a tractive effort equal to 25 per cent of the weight on drivers. The corresponding gross ton miles per hour are shown in parentheses at the head of the column. The gross ton miles obtainable under MAXIMUM TONNAGE conditions is the product of the tonnage and miles per hour just referred to.

"TRAILING TONS "B" The tonnages shown in the "B" column give the weight necessary to obtain the maximum gross ton miles per hour. The speeds and gross ton miles per hour corresponding to any grade will be found under the proper headings."

"TRAILING TONS 'A'" The tonnages shown in the "A" column are based upon a tractive effort equal to 25 per cent of the weight on drivers. The corresponding speed in m.p.h. is shown in parentheses at the head of the column. The gross ton miles obtainable under MAXIMUM TONNAGE conditions is the product of the tonnage and miles per hour just referred to.

"TRAILING TONS 'B'" The tonnages shown in the "B" column give the weight necessary to obtain the maximum gross ton miles per hour. The speeds and gross ton miles per hour corresponding to any grade will be found under the proper headings.

"TRAILING TONS 'A'" The tonnages shown in the "A" column are based upon a tractive effort equal to 25 per cent of the weight on drivers. The corresponding speed in m.p.h. is shown in parenthesis at the head of the column. The gross ton miles obtainable under MAXIMUM TONNAGE conditions is the product of the tonnage and miles per hour just referred to."

"TRAILING TONS 'B'" The tonnages shown in the "B" column give the weight necessary to obtain the maximum gross ton miles per hour. The speeds and gross ton miles per hour corresponding to any grade will be found under the proper headings."

\* Adhesion Limits may prevent the application of 40 HP per ton on Drivers, hence the performance listed under 30 per cent weight on drivers is doubtful.

To correct for small differences in boiler capacities assume the train weight remains constant and the speed is proportional to the boiler capacities. If there is a wide difference in boiler capacities the effect of differences in train resistance will be appreciable tending to increase or decrease the weight of train depending on whether the boiler capacities are less or greater than for the typical locomotive. Likewise the speed will be less than proportional to the horsepower capacities. For example, compare the tables for future designs of locomotives with normal designs column for column.

Having three classes of trains, adjustment can be made for differences in train resistance by interpolating between tables. Another way to correct for differences in train resistance is to express the difference in terms of grade, thus 2 pounds per ton difference in train resistance is equivalent to .1 per cent grade. The performance on level track would therefore correspond to that shown on a  $+.1$  or a  $-.1$  per cent grade, depending on whether the train resistance was 2 pounds per ton greater or less than assumed in Table 1 on page 895.

The trailing tons shown in column headed "A", Tables 2, 3 and 4, are the maximum tonnages which can be hauled on the various grades, assuming the locomotive is capable of exerting a tractive effort equal to 25 per cent of the weight on drivers. If the locomotive is equipped with a booster or auxiliary engine it may be able to start on the grades with the tonnages shown. If the engine is not equipped with a booster or auxiliary engine, it will only be able to negotiate short grades with the tonnages shown.

By comparing the tonnages in the "A" and "B" columns, it is possible to determine whether or not a locomotive can be loaded heavy enough on ruling grades to obtain the maximum gross ton miles per hour over some lower grades. Take, for example, the typical locomotive previously described. The weight of train which will give the maximum gross ton miles per hour on a .2 per cent grade has been shown to be 9.19 times the weight of the locomotive, including tender. This is slightly less than 9.40 found in the "A" column of the same table corresponding to a .7 per cent grade. If the ruling grade on the profile is .7 per cent or less, then it will be possible to operate a heavy enough train to produce the maximum gross ton miles per hour on a .2 per cent grade. If the ruling grade is greater than .7 per cent the tonnage which can be hauled will be limited by the ruling grade to something less than required to obtain the maximum gross ton miles per hour on a .2 per cent grade. In general, if the ruling grade is not more than .5 per cent greater than the average grade, then the profile will not limit the train weight below that required to obtain the maximum gross ton miles per hour on the average grade.

The speed in miles per hour corresponding to the maximum tonnages ("A" column) is given in parenthesis at the head of Column "A".

## (II) Comparison of Freight Train and Yard Performances

The purpose of this discussion in connection with the Committee's assignment is to study the effect of operating long or heavy freight trains upon yard switching performance. The present investigation is limited to a preliminary study of general statistics which may be extended later to specific cases.

A summary of statistics relating to freight train and yard performances for railroads in the United States by districts is given in Table 1 and plotted in Fig. 2, 3, 4 and 5. The table and charts show in some instances that the locomotive hours in freight switching service exceed the train hours on the road, or in other words, the work done in switching freight trains often requires more crew time than required to run them 100 miles on the road.

While this may not be a true measure of yard switching performance, it is nevertheless a condition which ought to attract considerable attention. It may be that Freight Train and Yard Performances are not strictly comparable, but it is logical to assume that on most railroads there is a tie between the two services when conditions are balanced.

The Association is familiar with the work of Sub-Committee 2 in the development of Freight Train Performance Charts as a means for showing the effect of new or improved facilities or the effect of increases or decreases in traffic upon freight train performance. Fig. 2 is one of these charts, which shows the changes that have taken place year after year since 1921 as the result of capital expenditure for new facilities or im-

RAILROADS IN THE UNITED STATES  
ALL DISTRICTS

FIG. 3

provements in operating methods. This chart also shows that Freight Train Performance has been maintained during the past three years notwithstanding all the efforts which have been made to combat the depression. During this latter period capital expenditures have been practically nil and the results obtained are exactly what would be expected from the theory developed several years ago by Sub-Committee 2.

Fig. 3 is a similar chart applied to yard switching performance and shows the switching locomotive hours per 100 train miles plotted against train miles and gross ton miles. By comparing Fig. 2 and 3, it will be seen that the changes which have taken place in yard switching performance since 1921 are small compared with the changes which have taken place in freight train performance. This may or may not be a natural condition. The point it is desired to bring out at this time is that yard performance varies with increases and decreases in traffic in the same manner as freight train performance, as indicated in the lower diagram of Fig. 3. Since train miles are not a measure of traffic, the upper diagram of Fig. 3 has practically no significance.

After a considerable study of statistics in order to find a suitable unit for measuring switching service the gross ton mile has been found to be the most practical. For the purpose of this discussion it seems unnecessary to adjust the reported gross ton miles for the increase in tare weight of freight cars and for the increase in average length of haul in order to have a truer measure of the duty performed by switching locomotives.

Fig. 4 gives a comparison of road time and switching locomotive hours per 100,000 gross ton miles by years and by districts to show the trends independent of the amount of traffic handled. In some ways it reflects the net results obtained from a general program of improvement from year to year. In individual cases it may be possible to go farther and analyze the results obtained from specific improvements.

Fig. 5 has been prepared for the purpose of indicating the progress which has been made in performance with respect to the operation of heavy trains. The hours road time per 100,000 gross ton miles have decreased between 1921 and 1930 as the average weight of trains increased. Since 1930 the average weight of trains has been decreasing while there has not been much change in the average road time per 100,000 gross ton miles, notwithstanding the fact that the amount of traffic has also decreased, which should tend to decrease the average road time. No doubt the present unusual economic conditions are the causes for the retrogressions which have taken place. If and when economic conditions improve data will be available for a more complete analysis from which it may be possible to determine the advantages or disadvantages of operating long heavy trains as regards yard switching performance.

(6) EFFECT OF VOLUME OF TRAFFIC ON RAILWAY  
OPERATING EXPENSES

S. W. Fairweather, Chairman, Sub-Committee; Miss Olive W. Dennis, J. M. Farrin, G. W. Hand, E. M. Hastings, C. H. R. Howe, M. F. Mannion, J. F. Pringle, Mott Sawyer, M. F. Steinberger, C. C. Williams, John Worley.

Students of railway expense have long realized that there exists a relationship between operating expenses and traffic, which is not completely reflected by the operating ratio. Very little study is required to prove that, other things being equal, the operating ratio of a railway is some function of the traffic density. This conclusion has found expression in various attempts to divide railway expenses into two parts, one designated as the fixed expense, and the second designated as variable expense. The division of operating expenses under these two groups in the past has been largely left to a common-sense judgment of the various items of expense, as developed in the primary expense classification of the Interstate Commerce Commission. The "Yager Formula" of the American Railway Engineering Association is an example of this form of treatment, having particular reference to maintenance of way and structures expenses.

The determination of fixed and variable expenses on the basis of common-sense judgment is open to the criticism that it is merely a guess. It is therefore possibly desirable to see to what extent the problem lends itself to statistical analysis, and inasmuch as there does not appear to have been submitted to the Association as yet any example of a statistical analysis on the basis of rectilinear correlation by the method of least squares, occasion will be taken during the process of the analysis to develop briefly the underlying theory.

As a preliminary to the analysis, a judgment of the factors which are to be considered must be made. Operating expenses and traffic density have already been mentioned, but capital investment per mile as a third factor must also be considered. A failure to include the effect of increasing capital investment upon operating expenses might tend to vitiate the result.

If the operating expenses of a road are susceptible, with a reasonable degree of accuracy, of being expressed by the equation of a plane, the equation, in simple form, would be

$$z = C + Ax + By$$

Where

$z$  = Operating expenses per mile of railway

$x$  = Traffic per mile, or in other words, the density of traffic

$y$  = Capital investment per mile

$C$  = A constant

The analysis will attempt to define the values of these constants and coefficients. In order to reduce to a minimum accidental variations in the data, all Class I roads of the U.S. are treated as a unit and the expenses for 1900 to 1929 inclusive are analyzed. It is recognized that in approaching the problem in this manner the difficulties inherent in handling a time series are incurred. These difficulties, so far as they arise from changes in price levels and wages, may be approximately allowed for by the application of index numbers reducing the data to a common price basis. On the other hand, the time series enables the analysis to include the effect of capital investment, which could not otherwise be done. The basic data for the analysis, therefore, consists in a tabulation of the miles of road, the traffic, the investment in road and equipment, operating expenses and the index of wages and cost of material, all of which are given on page 911.

TABLE 1

| <i>Year</i> | <i>Mileage<br/>(Oper.)</i> | <i>Traffic<br/>(Millions)</i> | <i>Expense<br/>(Millions)</i> | <i>Mileage<br/>(Invest)</i> | <i>Investment<br/>(Millions)<sup>1</sup></i> | <i>Index<br/>1913=100</i> |

These figures are based upon the Interstate Commerce Commission's statistics, but, of necessity, adjustments have been made in order to obtain reasonably comparable figures throughout the period. The traffic in millions of gross ton miles has been computed using the reported revenue ton miles (freight figures), the freight car miles and the passenger car miles, the average weight of freight cars and of passenger cars being applied to these figures. It may be interesting to note that the average weight of freight cars in the period increased from 14.9 tons in 1900 to 21.2 tons in 1929 and the average weight of passenger cars from 38.7 tons to 55.1 tons.

Prior to 1911 no distinction is made between Class I and Class II roads in the Interstate Commerce Commission statistics, and therefore up to and including 1910 the operating statistics relate to both Class I and Class II roads. Subsequent to that date the operating statistics relate to Class I roads. The mileage operated has been corrected for the elimination of trackage rights.

The investment figures and the mileage applicable thereto include Class I and Class II roads and their non-operating subsidiaries, and represent investment in road and equipment and improvements in leased lines. The figures are recognized as being approximate on account of the lack of continuity of strictly comparable data, but are nevertheless believed to be reasonably representative. The index relating costs to 1913 as a base is a composite of railway labour and railway material. In computing this index wages were given a weight of 65, iron and steel a weight of 5, timber a weight of 5 and miscellaneous materials a weight of 25.

Further treatment of the data requires a theoretical consideration of the theory of rectilinear correlation. For simplicity, consider the case of two variables  $y$  and  $x$ , such that  $y = f(x)$ . Since we are dealing with rectilinear correlation  $f(x)$  must be considered

as a straight line of the general equation  $y = mx + B$ . The analysis, therefore, becomes a problem of determining the value of  $m$  the slope of the line, and  $B$  the intercept of the line on the  $Y$  axis. The application of the analysis will usually be to data representing many particular cases of  $y$  in relation to  $x$ . For instance, there will be many particular cases of investment per mile in relation to traffic density per mile. If the data be plotted on rectangular coordinates, the various points, instead of lying smoothly along a straight line, will be found to be scattered somewhat, although by visual inspection it is apparent that a trend or tendency to a straight line exists. Quite obviously, this trend line must pass through the arithmetic mean of the  $x$  and  $y$  values, or to put it in another way, the average line must pass through the center of gravity of the points; but when we come to the question as to what the slope of the line should be, or indeed whether we are justified in drawing a conclusion that a straight line does reasonably satisfy the points in question, we are driven to a consideration of the law of probabilities. According to the law of probabilities, the most probable value of a series of observations is that value which will make the sum of the squares of the differences between it and the observed values a minimum. This value is the arithmetic mean of the data and is the reason why the center of gravity of all the points must lie on the mean line. Similarly, the most probable mean line is defined as the one with regard to which the sum of the squares of the distances of the observed points from the mean line is at a minimum. It is from this characteristic that the term "Method of Least Squares" is derived. It should be noted that, generally speaking, the slope of the mean line will differ depending upon whether the line is fitted to produce the minimum squares of the  $y$  differences or the minimum squares of the  $x$  differences.

Since the relation to be discovered is the most probable value of  $y$  in relation to variations of  $x$ , the trend line will be fitted in such a manner as to produce the minimum sum of the squares of the  $y$  differences. To fit the line to the points, let a subsidiary set of co-ordinates be passed through the center of gravity of the points. (See diagram below.)

The value of the  $y$  difference on the new set of co-ordinates between any given point and a point on the desired trend line having the same  $x$  value is

$$y \text{ difference} = \bar{y}_p - \frac{\bar{x}_p \bar{y}_a}{\bar{x}}$$

Where  $\bar{y}_p$  and  $\bar{x}_p$  are the co-ordinates of the point referred to the new axis,  $\bar{y}_a$  is the  $\bar{y}$  value of the intercept between the new  $\bar{X}\bar{X}$  axis and the trial line on the  $YY$  axis, and  $\bar{x}$  is the  $x$  value of the new axis. The sum of the squares of the differences is therefore:

$$\Sigma (y \text{ differences})^2 = \Sigma (\bar{y}_p^2) - \Sigma \left( \frac{2\bar{y}_p \bar{x}_p \bar{y}_a}{\bar{x}} \right) + \Sigma \left( \frac{\bar{x}_p^2 \bar{y}_a^2}{\bar{x}} \right)$$

Differentiating  $\Sigma (y \text{ differences})^2$  with regard to  $\bar{y}_a$  and equating to zero to obtain a minimum value of the squares of the  $y$  differences, we obtain:

$$\frac{2\bar{y}_a}{\bar{x}^2} \Sigma (\bar{x}_p^2) - \frac{2}{\bar{x}} \Sigma (\bar{y}_p \bar{x}_p) = 0$$

$$\text{whence } \frac{\bar{y}_a}{\bar{x}} = \frac{\Sigma (\bar{y}_p \bar{x}_p)}{\Sigma (\bar{x}_p^2)}$$

$\frac{\bar{y}_a}{\bar{x}}$  is the slope of the most probable trial line and the intercept of this line on the  $Y$  axis is  $\bar{y} - y_a$ . The values of  $m$  and of  $B$  in the basic equation therefore have been determined in such a manner as to satisfy the law of least squares and therefore the law of probabilities. Assuming a normal frequency distribution of the points about the mean line, which is a reasonable assumption where there is a large number of points, it is possible to deduce certain relationships which test the reasonableness of the basic assumption that  $y$  is a rectilinear function of  $x$ . The square root of the sum of the squares of the differences furnishes a test of the probable error. It is analogous to the radius of gyration in mechanics. The probable error, assuming a normal frequency distribution, is equal to  $\frac{.67 \sqrt{\Sigma (y \text{ differences})^2}}{N}$ ,  $N$  being the number of points. It simply means that any particular value of  $y$  has an equal chance of being nearer to the mean value than further away from it. In other words, 50 per cent of all the  $y$  values will be no further away than this amount from the mean.

For instance, the probable error of a horizontal line through the mean of the  $x$  and  $y$  values may be tested by this formula, the  $y$  difference in this case being the  $\bar{y}$  co-ordinates of the points; likewise, the probable error of the line fitted by the method of least squares may be determined, in this case, the  $y$  difference being the differences between the  $\bar{y}$  co-ordinates of the points and the  $\bar{y}$  co-ordinates of points on the line having the same  $x$  value. If it is found that the probable error with regard to the line fitted by the method of least squares is smaller than the probable error of a horizontal line, it shows that we have improved the accuracy of the fit by rotating the line to the value where  $m = \frac{\Sigma \bar{x}\bar{y}}{\Sigma \bar{x}^2}$ . Likewise, a comparison of the reduction in the probable error affords some measure of the reasonableness of the fit.

This relationship between these two probabilities has been expressed in terms of what is called the correlation factor, which is an absolute numerical expression of the

degree to which  $y$  may be said to vary with  $x$ , taking into account the dispersion of the points. The correlation factor of which the standard symbol is  $r$  is equal to

$$\sqrt{1 - \frac{(\text{the probable error of the fitted line})^2}{(\text{the probable error of a horizontal line})^2}}$$

From this equation it is apparent that all values of the coefficients of correlation must lie between 0 and 1. If the value is 1, it means that all the points fall accurately on the line in question; if the value is 0, it means either that the dispersion is so great that any line fits the data as well as any other line, or that the points fall accurately on a line parallel to the  $x$  axis, in which latter case of course  $y$  would not vary with  $x$ . For reasonably accurate treatment of the statistical data by rectilinear correlation, the value of  $r$  should be reasonably high. Values above .9 are quite satisfactory.

There are statistical short cuts for the determination of  $m$  and  $B$ , as well as for the determination of the probable error and of the coefficient of correlation, which may be obtained from any modern work on statistical methods.

Inasmuch as the problem at hand is to develop the relation between operating expenses and traffic density and investment in road and equipment, it will be necessary to deal with three-dimensional co-ordinates and the data must be considered as points in space referred to three planes mutually at right angles. It will be convenient to consider the horizontal or  $XY$  plane as representing relationship between traffic density and unit investment in road and equipment, and the  $ZX$  plane and the  $ZY$  plane as representing the relationship between unit operating expenses  $z$ , traffic density  $x$ , and unit investment in road and equipment  $y$ . The  $x$ ,  $y$  and  $z$  values representing the conditions for all Class I roads 1900-1929 are as follows:

TABLE 2

| <i>Year</i> | <i>x</i><br><i>Traffic</i><br><i>Density</i> | <i>y</i><br><i>Unit</i><br><i>Investment</i> | <i>z</i><br><i>Unit</i><br><i>Expense</i> |
|-------------|----------------------------------------------|----------------------------------------------|-------------------------------------------|
| 1900        | 2,233                                        | \$ 72,940                                    | \$ 6,630                                  |
| 1901        | 2,189                                        | 73,391                                       | 6,770                                     |

$x$ —Thousands of Gross Ton Miles per Mile.

$y$ —Adjusted Investment per Mile = Investment as of 1900 divided by price-wage index for 1900, plus total, to date, of increases for each subsequent year divided by price-wage index of corresponding year.

$z$ —Adjusted Operating Expense per Mile = Actual Expense divided by price-wage index.

By the method outlined above, the most probable plane which can be passed through the mean value of the points and be perpendicular to the  $ZX$  plane, may be determined, detail calculation being as follows:

$z$  = Unit Expense in Thousands of Dollars per Mile.

$x$  = Traffic Density in Millions of G.T.M. per Mile.

$N$  = Number of cases (years) considered.

$$\bar{x} = x - \frac{\Sigma(x)}{N}$$

$$\bar{z} = z - \frac{\Sigma(z)}{N}$$

$$m = \frac{\Sigma(x\bar{z})}{\Sigma(\bar{x}^2)}$$

$$d = \bar{z} - m\bar{x}$$

| Mean  | 1.366       |            |       | .358   | 1.412       |

The equation of this plane is  $z = .879 + 5.545$

The probable  $z$  error with regard to this plane is .404 as compared with the probable  $z$  error of .801 with regard to a horizontal plane through the mean value or centre of gravity of the points. The correlation factor is reasonably high, being .864. Therefore the plane  $z = .879 + 5.545$  fits the points reasonably well. Similarly, the most probable plane passing through the mean of the  $z$  values perpendicular to the  $ZY$  axis may be determined. By calculation similar to the above, it develops  $z = .801y + 1.976$ . The probable error of the  $z$  values with regard to this plane is .467. The probable error with regard to a horizontal plane remains as before .801 and again the plane is seen to fit the points reasonably well, the correlation factor being .813. The intersection of these two planes defines a straight line in space, the graphical representation of which is shown upon Graphs, Diagrams 1, 2 and 3.

This line of course passes through the mean of the  $x$ ,  $y$  and  $z$  values, which is

$x = \text{Traffic density} = 4.064$

$y = \text{Investment per mile} = 8.913$

$z = \text{Operating expenses per mile} = 9.118$

$x$  being measured in millions of equivalent gross ton miles,

$y$  in tens of thousands of dollars equated to 1913 value, and

$z$  in thousands of dollars equated to 1913 value.

The average line punctures the  $ZY$  plane at a  $y$  value of 4.453, with a  $z$  value of 5.545, the value of  $x$  being 0. This might be interpreted as meaning that the investment

in a road equipped to do business but as yet having no business, would be \$44,530 (equated) per mile and the operating expenses would be \$5,545 per mile, being of course all fixed.

The next step is to determine whether there is any particular plane which can be passed through this line which will fit the data in such a manner as to produce a still lower probable error of the  $z$  values than the planes which were passed at right angles to the  $ZX$  and  $ZY$  planes. To test this a reference plane may be passed through the line in such a manner that lines in the plane at right angles to the average line are parallel to the  $XY$  plane. The equation of this plane is  $z = 3.60 + .399x + .437y$ .  $z$  differences between the points and this plane may then be determined and the degree to which the plane should be rotated to produce a minimum sum of the squares of the  $z$  differences can be investigated.

By a process similar to that which has already been developed, it may be shown that the tilt of the plane normal to the axis, to produce the minimum sum of the squares of the distances between the points and the tilted plane is determined by the ratio  $\frac{\Sigma(\delta z \times h)}{\Sigma(h^2)} \times \cos \phi$  where  $\delta z$  is the vertical distance between any point and the plane,  $h$  is the perpendicular distance measured in the  $XY$  plane between the trace of the point and the trace of the axis, and  $\cos \phi$  is the cosine of the angle made between the axis and the  $XY$  plane. For convenience, the degree of dispersion about the axis may be plotted to oblique co-ordinates. In this projection the axis will appear as a point, the reference plane will appear as a horizontal line, and  $\delta z$  will appear as ordinates above or below the horizontal line. The planes which have previously been investigated, one at right angles to the  $ZX$  plane, and the other at right angles to the  $ZY$  plane, are shown on the graph, Diagram No. 4, as well as the plane which produces the minimum  $\Sigma(\delta z^2)$ . The equation of this plane related to the original axis of co-ordinates is  $z = 8.05 + 1.496x - 0.562y$ . The probable  $z$  error of this plane is .388 as compared with a probable error of the data at large of .801, and the correlation factor is .877.

In using this formula, it must be borne in mind that it is only applicable to cases where the  $x$  and  $y$  values, i.e. the traffic density and the investment per mile, approximately satisfy the equation  $y = 1.097x + 4.453$ . If an attempt is made to apply the formula to values of  $x$  and  $y$  very far from this condition, the data would be forced to an unwarranted extent. Keeping in mind this limitation, it will be seen that the equation confirms the general experience that operating expenses are decreased by an increase in investment, the equation showing that an increase of \$10,000 per mile in capital expenditures would produce a decrease in operating expenses of \$560 per mile. It is interesting to compare this result with the average interest rate of say  $5\frac{1}{2}$  per cent which would add \$550 to the fixed charges, but it must be kept in mind that in addition to enabling the reduction in operating expenses to take place, the additional investment also increases the capacity of the property.

From these equations it is possible to determine the percentages of operating expenses which are fixed and variable at a given traffic density, certain qualifications being taken into account. The first of these is that the determination applies to an increase in traffic density and not to a decrease. The second is that it applies to normal average conditions, the third that it implies increasing investment at the amount of \$10,970 per million equated gross ton miles. The equation for operating expenses under these assumptions is  $z = .879x + 5.545$ . The increment in expense per million equivalent gross ton miles is .879 (\$.879) per mile of road,  $z$  may be divided into  $z_f$ ,  $z_v$ ;  $z_f$  being the fixed expense and  $z_v$  the variable expense. Since we are dealing with a straight line,  $z_f$

is  $B$  and  $zx$  is  $mx$  in the general equation  $z = mx + B$ . The percentage of expense which is proportional to increased traffic at any traffic density  $x$  is therefore  $\frac{mx}{mx + B}$ . For various traffic densities and for the stated average investment per mile of line, the proportion of expenses which is variable is therefore as follows:

TABLE 4

| Traffic Density<br>(Millions) | Normal<br>Investment<br>per mile | Per Cent<br>Expense<br>Variable<br>with Traffic | Per Cent<br>Expense<br>Fixed |
|-------------------------------|----------------------------------|-------------------------------------------------|------------------------------|
| 2 .....                       | \$ 66,500                        | 24.1                                            | 75.9                         |
| 3 .....                       | 77,500                           | 32.2                                            | 67.8                         |
| 4 .....                       | 88,500                           | 38.8                                            | 61.2                         |
| 5 .....                       | 99,000                           | 44.2                                            | 55.8                         |
| 6 .....                       | 110,000                          | 48.7                                            | 51.3                         |
| 7 .....                       | 121,000                          | 52.6                                            | 47.4                         |

A final word of caution might be added. It must not be inferred that the result is applicable to sudden changes in traffic density, either increases or decreases. What has been accomplished is to give statistical expression to the historical development of U.S. Roads for the 30 years between 1900 and 1929 in relation to increasing traffic density and increasing investment in property. The method which has been used is applicable to many cases of statistical analysis and has the merit that it avoids the perils connected with the forcing of data to yield conclusions which cannot be supported.

As a practical application of the analysis, let it be supposed that a railway with traffic density 6,000,000 gross ton miles per mile with approximately the normal capital relationship had an operating ratio of .75, what might be the effect of a 10 per cent increase in traffic on the operating ratio?

By reference to Table 4 it will be seen that on such a road 51.3 per cent of the expenses are fixed and 48.7 per cent are variable. The operating ratio under the new conditions would therefore be:

$$\frac{.75}{1.10} \left\{ .513 + (1.10 \times .487) \right\}$$

This equals .715 so that the increase of 10 per cent in traffic under these conditions would produce a decrease in the operating ratio of .035.

Another application follows: A road with a traffic density of 6,000,000 gross ton miles per mile and with an operating ratio of .75, having experienced up to that time the average trend of capital expenditures decides to put no additional capital into the property; an increase in traffic of 10 per cent occurs—what would the operating ratio be?

Referring to Table 4, and substituting 6.0 for the value of  $x$  (traffic density in million gross ton miles), and 11.0 for the value of  $y$  (investment per mile of road in tens of thousands of dollars), in the basic equation  $z = 8.05 + 1.496x - 0.562y$ , as developed on page 917, the value of  $z$  (operating expenses per mile) may be determined in units of one thousand dollars. Solving this equation,  $z = 8.05 + 1.496 \times 6.0 - 0.562 \times 11.0$ .  $z = 10.844$ , or \$10,844.

With a 10 per cent increase in traffic and no increase in investment, the equation becomes  $z = 8.05 + 1.496 \times 1.10 \times 6.0 - 0.562 \times 11.0$ .  $z = 11.741$ , or \$11,741.

The corresponding operating revenue per mile with an operating ratio of 0.75 is equivalent to \$10,844  $\div$  0.75, or \$14,459. With a 10 per cent increase in traffic, the corresponding operating revenue is equivalent to 14,459  $\times$  1.10, or \$15,905 per mile. The operating ratio with a 10 per cent increase in traffic, therefore, would be 11,741  $\div$  15,905, or 0.738.

### *To the American Railway Engineering Association:*

Your Committee respectfully presents reports on the subjects assigned, as follows:

- (1) Revision of Manual (Appendix A).
- (1-A) Specifications for soft steel track spikes (Appendix B).
- (2) String lining of curves by the chord method, and preparation of tables suitable for the use of trackmen (Appendix C).
- (3) Plans and specifications for track tools, collaborating with Committees I—Roadway, II—Ballast, and XXII—Economics of Railway Labor (Appendix D).
- (4) Plans for switches, frogs, crossings, slip switches, etc. (Appendix E).
- (5) Track construction in paved streets, collaborating with Committee IX—Grade Crossings (Appendix F).
- (6) Corrosion of rail and fastenings in tunnels, collaborating with Committee IV—Rail (Appendix G).
- (7) Gage of track and elevation of curves with reference to the use of roller bearings on railway equipment, collaborating with the Mechanical Division of the A.R.A. (Appendix H).
- (8) Effect of existing materials in track on the design of tie plates and punching thereof, together with the interrelation of slotting of joint bars and size of track spikes, collaborating with Committee IV—Rail (Appendix I).
- (8-a) Design of tie plates for RE Rail Sections (Appendix I-1).
- (9) Practicability of using "Reflex" units for switch lamps and targets, collaborating with Committee X—Signals and Interlocking (Appendix J).
- (10) Selective welding up at joints, instead of welding out of face (Appendix K).
- (11) Desirable tightness of track joints and effect upon the life of rails and joints of overtight joints; of loose joints (Appendix L).
- (12) Reclamation of serviceable materials from scrap and retired maintenance of way and structure machines, tools and appliances, collaborating with Division VI—Purchases and Stores, A.R.A. (Appendix M).

(13) Methods of reconditioning of rail ends, fastenings, frogs and switches in track (Appendix N).

(14) Determination of the limiting relative positions of the abutting rails of fixed and drawspans on bridges and proper tolerances, collaborating with Committee X—Signals and Interlocking, XV—Iron and Steel Structures, and with Signal Section (Appendix O).

(15) Damage to track and devices due to brine drippings from refrigerator cars, collaborating with Mechanical Division, A.R.A. (Appendix P).

### Action Recommended

(1) That revisions recommended in Appendix A be approved for publication in the Manual.

(2) That additions to the specifications for soft steel cut track spikes and malleable iron tie plates in Appendix B be adopted as recommended practice and published in the Manual, and that plans for 9/16 in. and 5/8 in. raised throat cut track spikes be received as information.

(3) That plans A, B, C-1, C-2, D-1, D-2, D-3, E, F, 21 and 22 in Appendix D be adopted as recommended practice and published in the Manual, and that plan 31, with study plans A and B, be received as information.

(4) That plan 505 in Appendix E be adopted as recommended practice and published in the Manual.

(5) That plans, Fig. 1 to 8, inclusive, in Appendix I be adopted as recommended practice and published in the Manual.

(6) That report in Appendix F be received as information.

(7) That report in Appendix H be received as information and the subject discontinued.

(8) That report in Appendix J be received as information.

(9) That report in Appendix K be received as information and the subject discontinued.

(10) That report in Appendix L be received as information and the subject discontinued.

(11) That report in Appendix N be received as information.

(12) That report in Appendix P be received as information and the subject discontinued.

(13) That progress reports in Appendices C, G, M and O be received as information.

Respectfully submitted,

THE COMMITTEE ON TRACK,

C. J. GEYER, *Chairman*.

### Appendix A

#### (1) REVISION OF MANUAL

C. J. Geyer, Chairman, Sub-Committee; W. G. Arn.

The Committee recommends:

That the material shown under the headings "Table of Dimensions for Tie Plates" and "Data for Designing Tie Plates", on page 251 of the 1929 Manual, be withdrawn.

The Committee proposes as recommended practice, that the design of cut track spikes, appearing in the Manual at page 254, be revised as follows:

The elimination of the dimensions which provide for optional lengths of spikes and in substitution therefor incorporation of dimensions providing for a single length of  $5\frac{1}{2}$  in. between the throat and point for 9/16 in. spikes, and a single length of 6 in. for  $\frac{5}{8}$  in. spikes.

The Committee also recommends the withdrawal of track tool plans Nos. 1, 2, 3, 5, 6, 9, 11, 12, 13, 14, 15, 16, 18, and 19 adopted in 1930 and substitution of plans of like numberings herewith submitted.

The Committee deemed it advisable to review the plans, hereto approved, that now appear in the Book of Trackwork Plans, with the result that practically all of them have been revised. The principal revisions consist of:

Withdrawing Plans Nos. 271 to 279 inclusive, 281 to 283 inclusive, 291 and 292 and substituting therefor a new series of plans bearing the same numbers. The original plans show frogs for heavier rails up to 150 lb. per yard; at the present time the railroads are generally considering only rails weighing not more than 131 lb. per yard, consequently the new series of plans show frogs of considerably shorter lengths.

The March, 1933, Index Supplement, pages 4, 5, and 6, of the Book of Trackwork Plans describes a large number of approved revisions; these revisions have been made on the plans now being submitted, and this Index Supplement is now being withdrawn.

The Specifications for Switches, Frogs, Crossings and Guard Rails contained in Appendix B of the book of Trackwork Plans have been revised and enlarged to include pertinent data from the Specifications for Special Trackwork Materials, approved by the American Standards Association under its No. E10-1929.

In addition to the above, numerous other revisions of a minor character have been made on the plans for the sake of consistency and to bring them up to date.

Copies of the revised Book of Trackwork Plans with new Index will be available in the office of Secretary E. H. Fritch, after February 1, 1934, for examination.

The Committee recommends that the revisions outlined above be approved.

The Committee recommends the revision of Plans 780, 781 and 980, dated November, 1926, adopted March, 1927, by the substitution of revised plans of the same numbers, dated March, 1934. The revisions to the respective plans consist of the following:

Plan 780: Title revised to read:

Solid Manganese Steel Crossings for 7-in. and 9-in. Girder Rails  
Steam Railroad over Electric Railway  
(See note for Steam Railroad Tracks Both Ways)

Addition to the plan of the following note:

"When girder rail crossing carrying steam traffic over both runs is desired the details through both runs shall be in accordance with those here shown for "steam run" and the necessary joints within the diamond of the crossing shall accord with the details shown on Plan 771 for such joints.

"When it is desired to modify the arms to connect with 'T' rails, details for such arms should follow details prescribed on Plan 771.

"For complete rules for laying out details of crossing see Plan 700."

Plan 781: Title revised to read:

Solid Manganese Steel Crossings for 7-in. and 9-in. Girder Rails  
Steam Railroad over Electric Railway  
(See note for Steam Railroad Tracks Both Ways)

Addition to the present note on the plan of the following:

(The same information as given above for Plan 780.)

In addition to the above add to the note:

"If either track has a center line radius of less than 995-ft. (6 degrees) the end frogs must be suitably guarded on the curved track."

Plan 980: Note revised to read:

"For Straight Double Tongue Switches, suitable for situations where equipment having rigid wheel base of not more than 14 ft. 6 in. with two or three pairs of flanged wheels is used, see Plan 987.

"For Straight Double Tongue Switches, suitable for situations where equipment having rigid wheel base of not more than 19 ft. 0 in. with three, four or five pairs of flanged wheels is used, see Plan 988.

"For Curved Tongue Switch and Mate for industrial tracks, suitable for situations only where equipment having rigid wheel base with not more than two pairs of flanged wheels is used, see Plan 982."

The Committee recommends the revision of Plan 983, revised November, 1927, adopted March, 1928, and Plans 984, 985, and 986, dated November, 1927, adopted March, 1928, by the substitution of revised plans of the same numbers dated March, 1934. The revision to the respective plans consists of the addition to the note on each plan of the following:

"Wheel riser as per Plan 600-A shall be furnished when so specified."

Where necessary, the revisions to the plans referred to above shall include the showing of all dimensions less than 2 feet, in inches, and 2 feet and over, in feet and inches.

The Committee recommends the revision of Plan 982, dated February, 1930, adopted March, 1930, by the substitution of a revised plan of the same number, dated March, 1934.

The revisions consist of the following:

A. On General Plan—Switch:

- (a) Changing dimension of 4 in. for width of tongue at 4 in. back from point end to 3  $\frac{61}{64}$  in.
- (b) Deleting dimension of 1 in. for thickness of guard of tongue at Section C-C.
- (c) Moving letters C-C for section to bend at 2 ft. 7 in. back from point of tongue.
- (d) Adding note at line 1 ft. 4 in. back from point of tongue "Center line of lug if specified".
- (e) Deleting the dimension of 1 in. for width of guard and 1 in. for opening between guard and switch piece at the bend near heel of switch.
- (f) Changing dimension of 3 ft.  $0\frac{7}{8}$  in. distance from center of pin to bend to 3 ft.  $6\frac{1}{2}$  in.
- (g) Adding dimension of 4 in. for distance from theoretical gage line to face of wall of switch piece at the bend 3 ft.  $6\frac{1}{2}$  in. from center of pin.
- (h) Adding note "Face of wall of switch piece parallel with theoretical gage line and 4 in. therefrom".
- (i) Change dimension of 1 in. for thickness of guard of tongue where it joins the heel of switch to  $\frac{3}{4}$  in.
- (j) Adding note "Switch for Right Hand Turnout as drawn".

B. On large size Section C-C deleting dimension of 1 in. for width of guard side of tongue and also deleting shade lines to indicate chamber.

C. On large detail drawing of point end of tongue:

- (a) Moving letters C-C to 2 ft. 7 in. back from point of tongue at location marked "Bend".
- (b) Adding dimension 3  $\frac{61}{64}$  in. for out to out width of tongue at 4 in. back from point end.

- (c) Changing dimension of 1 in. for width of tongue on tread side 4 in. back from point end to 61/64 in. and correcting arrow for this dimension to extend to theoretical gage line of tongue instead of actual gage line as now shown on the plan.

D. On General Plan—Mate:

- (a) Moving "BEND" on guard from 5 ft. 9 in. to 3 ft. 6 in. back from toe end and changing dimension 5 ft. 9 in. to 3 ft. 6 in.
- (b) Moving dimension 2¼ in. for flangeway width from 5 ft. 9 in. to "BEND" at 3 ft. 6 in. back from toe end.
- (c) Deleting the two dimensions 1¼ in. shown for distance from theoretical gage line in turnout run to guard line, between the "BEND" and the point of the mate.
- (d) Changing dimension 4 ft. 5 in. to 4 ft. 4 in. Guard to Guard.
- (e) Deleting the notation "P.C.C. on Guard" at point of mate, and the two radii of the guard, "Rad. 55' 0"" and "Rad. 202' 2¾"".
- (f) Adding dimension 2¼ in. from theoretical gage line in turnout run to guard line, at 1⅝ in. point of mate.
- (g) Adding information to clearly show that between the "BEND" at toe end, and beginning of flare at heel end, the guard line is a 3 point curve, passing through the point 2¼ in. away from actual gage line at "BEND" 3 ft. 6 in. from toe end, the point 2¼ in. from theoretical gage line at 9 in. in from heel end, and the point 2¼ in. from theoretical gage line at 1⅝ in. Point of Mate.
- (h) Inserting word "ACTUAL" between "4' 8¼"" and "GAGE" at dimension line 6 in. ahead of Point of Mate.
- (i) Adding note "Mate for Right Hand Turnout as drawn".

E. In large detail of Mate Point, changing dimension 1¾ in. at end of Point in Turnout run to 2¾ in.

F. In Section E-E, changing 1¾ in. dimension for width of flangeway in turnout run to 2¾ in.

Where necessary the revisions referred to above, shall include the showing of all dimensions less than 2 feet, in inches and 2 feet and over in feet and inches.

The revised issue of the Portfolio of Trackwork Plans, available in the Secretary's office, include the plans with revisions above referred to.

## Appendix B

### (1-A) SPECIFICATIONS FOR SOFT STEEL TRACK SPIKES

E. D. Swift, Chairman, Sub-Committee; J. E. Deckert, F. J. Jerome, F. H. Masters, E. M. T. Ryder, J. R. Scatterday.

The Committee offers the following additional sections for inclusion in the Specifications for Soft Steel Cut Track Spikes, now appearing in the Manual at page 252.

#### TENSION TESTS

(a) The manufacturer may, at his option, substitute tension tests for the chemical analysis specified in Section 2, in which case the finished spikes shall conform to the following minimum requirements as to tensile properties:

|                                       |                      |
|---------------------------------------|----------------------|
| Tensile strength, lb. per sq. in..... | 55,000               |
| Yield point, lb. per sq. in.....      | 0.5 tensile strength |
| Elongation in 2 in., per cent.....    | 25                   |

(b) When this option is exercised, one tension test shall be made from each 10-ton lot or fraction thereof.

## COPPER CONTENT

When copper is specified the percentage contained in the steel shall be not less than 0.20 of 1 per cent.

The Committee presents plans of  $\frac{1}{8}$  in. and  $\frac{5}{8}$  in. raised throat cut track spikes as information and for criticism pending their proposed later resubmission as recommended practice.

The Committee offers as information and for criticism pending its proposed resubmission as recommended practice a proposed revision of the Specifications now appearing in the Manual for Malleable Iron Tie Plates to consist of substituting the following requirements on tensile strength for the requirements now stated in the Specifications:

|                                       |        |
|---------------------------------------|--------|
| Tensile strength, lb. per sq. in..... | 53,000 |
| Elongation in 2 inches, per cent..... | 18     |
| Yield point, lb. per sq. in.....      | 35,000 |

$\frac{5}{8}$  INCH RAISED THROAT TRACK SPIKE.

9/16 INCH RAISED THROAT TRACK SPIKE.

## Appendix C

## (2) STRING LINING OF CURVES BY THE CHORD METHOD AND PREPARATION OF TABLES SUITABLE FOR THE USE OF TRACKMEN

C. M. McVay, Chairman, Sub-Committee; L. H. Bond, C. W. Breed, F. S. Hales, J. E. Hogan, E. T. Howson, C. J. Rist.

The Committee reports progress. Additional information on this subject is not developed sufficiently to warrant a report this year.

## Appendix D

### (3) PLANS AND SPECIFICATIONS FOR TRACK TOOLS

W. L. Roller, Chairman, Sub-Committee; W. H. B. Bevan, H. R. Clarke, L. W. Des-Lauriers, F. S. Hales, E. T. Howson, J. R. Scatterday, G. M. Strachan.

In the Proceedings, Vol. 31, 1930, pages 555 to 587 inclusive, the Committee submitted the following as information and for further study:

1. General Specification for Track Tools.
2. Specification for Hickory Handles for Track Tools.
3. Plan and Specification for Track Shovels.
4. Plan and Specification for Ballast Forks.

Since that time, in collaboration with the tool manufacturers, the Committee has revised these plans and specifications and now presents them for adoption and printing in the Manual.

Committee presents for information, a design for Frog and Crossing Limit Gage, together with instructions for the use of same.

### Conclusions

Committee recommends for adoption as recommended practice and printing in the Manual the following Specifications and Plans:

1. General Specifications A.R.E.A. track tools, Plans A, B, C-1, and C-2.
2. Specifications for Hickory Handles A.R.E.A. Track Tools, Plans D-1, D-2, and D-3.
3. Specifications for A.R.E.A. Track Shovels, Plan E.
4. Specifications for A.R.E.A. Ballast Forks, Plan F.
5. Plan No. 21 dated Sept. 1933, A.R.E.A. Track Shovel.
6. Plan No. 22 dated Sept. 1933, A.R.E.A. Ballast Fork.

Committee wishes to submit following correction to report of 1930 Proceedings Vol. 31, page 587 in Conclusions "Plan 21 dated Sept. 1929 A.R.E.A.—Wooden Track Tool Handles" should be revised to read "Plan 25—Dated Sept. 1929, A.R.E.A. Track Tool Handles."

Committee submits a design of Frog and Crossing Limit Gage for use in maintenance in accordance with Plan 790 adopted in 1933 as a result of study made of Standard Wheel Flanges, Treads and Gages. The design (Plan 31) as submitted is to be used only at crossings and frogs to show proper gages for the use of chilled car wheels and heavy engine drivers.

The plan is submitted, along with instructions and study, Plans "A" and "B" for information only.

Committee recommends the subject be continued by making further study and design of additional tools adapted to use in modern track construction and maintenance, particularly as regards tools used in laying and handling of heavier rails.

### INSTRUCTIONS FOR USING THE FROG AND CROSSING LIMIT GAGE AS OUTLINED ON A.R.E.A. PLAN NO. 790

(1) The Frog and Crossing "Limit Gage" is intended primarily to be used to check worn track at turnouts and crossings so that flangeways and guard rails may be maintained so that wheels properly gaged will pass freely without causing track distortion and without causing axles to be bent, or causing wheels to mount rails.

#### NOTES

For dimensions not shown and for accurate finished dimensions required, see outline of Frog and Crossing Limit Gage, Plan No. 799.

Gage A may be taken down and assembled to a 2'-31 1/2" length with wood strips between the two cast aluminum ends, inserting the four cap screws through the four holes provided for this purpose.

Wood strips shall be of mahogany or other approved hard wood.

PLAN No. S-93310

wor  
tain  
and

(2) The "NOT GO" gage, illustrated in the upper half of the Frog and Crossing Limit Gage is similar to a standard gage used for setting guard rails to protect the frog point. When "frog point end" is in contact with the worn frog, the guard rail end must "NOT GO" into flangeway.

(3) The "GO GAGE", illustrated in the bottom half of the gage, will fit freely in new track work properly installed, or in worn track work where the flangeways are not less than  $1\frac{5}{8}$  in. wide, and the guard face gage does not exceed 4 ft. 5 in., and where the track gage is not less than 4 ft.  $8\frac{1}{4}$  in. These have been accepted as the limiting dimensions for properly maintaining worn track.

(4) In checking crossings (especially those near 90 degree intersection angle), this "GO GAGE" will readily detect flangeways which should be ground out to maintain the proper clearance. The tendency is for the flangeways in crossings to narrow at intersections, due to the flow of metal from the tread surfaces. This is especially noticeable where traffic predominates over one line, and the flangeways on the less used track line close.

(5) Attention to the correct adjustment of the guard rail opposite the frog point of turnout will permit the frog flangeways to close-in to  $1\frac{5}{8}$  inches width without track distortion resulting when wheels pass through. This is clearly exhibited on study plans "A" and "B", showing conditions with open-hearth guard rails of T rail head and manganese guard rails having a head of special form approximately  $\frac{1}{4}$  in. higher than running rail.

Diagram 1 in each case shows the frog and crossing limit gage fitting freely into the flangeways of the new track.

Diagram 2 in each case shows the guard rail properly set for  $1\frac{5}{8}$  in. frog flangeway, and the frog and Crossing Limit Gage fitting into the flangeways.

Diagram 3 in each case shows what to avoid if relining track in condition shown in diagram 2. If the gage is widened and the guard rail is pulled out with the track rail, an excessive "guard-face-gage" (as shown in this diagram) will result; in this case it is evident that track distortion will occur when every pair of wheels passes through, unless the wheels climb or their axles bend.

\* No Hardness Specification for Alloy Steel.

## PLAN B

## TRACK TOOLS

## GENERAL SPECIFICATIONS

## WORKMANSHIP AND FINISH

Each tool shall be finished in a workmanlike manner and shall be free from seams, cracks, irregularities of shape and other imperfections. Before leaving the factory, each tool shall be coated with paint, oil or varnish to prevent corrosion, and each polished cutting edge shall be oiled.

## MARKING:

Each tool shall be plainly stamped with the manufacturer's name or brand and the purchaser's initials.

## INSPECTION AND TESTS:

Inspection of finished tools may, at the option of the purchaser, be made at the plant prior to shipment and the manufacturer shall afford the inspector, free of cost, all reasonable facilities to enable him to satisfy himself that the tools are in accordance with the plans and specifications. The tests and inspection shall be so conducted as not to interfere unnecessarily with the operation of the works. Unless otherwise specified, the inspector shall select and test one finished tool from each lot of ten dozen or less, and the acceptance or rejection of each lot shall be determined by the results of this test.

In the detail specifications, the permissible variations are not to be construed to change the shape and general contour of the tool as indicated on the plans.

When Brinell hardness tests are specified, other recognized bases of measurement may be used, provided equal results are obtained.

## SHIPMENT OR DELIVERY:

Tools shall be properly packed for shipment to avoid damage. All bundles and boxes shall be plainly marked with the name of the purchaser, the name of the manufacturer, and the point of shipment.

## MANUFACTURER'S GUARANTEE:

The manufacturer shall guarantee that all tools are free from defects in material and workmanship and shall replace any tools found to be defective.

## PLAN C-1

INSPECTION AND PHYSICAL TESTS

## CLAY PICK - PLAN NO. 1: (Open Hearth Steel or Alloy\*)

Dimensions, length, size of eye and curve or anchor of pick to be as shown on the plan. Brinell 425 to 500 at a point 1-1/2" from each end.

## TAMPING PICK - PLAN NO. 2: (Open Hearth Steel or Alloy\*)

Dimensions, length, size of eye and curve or anchor of pick as shown on plan. Brinell 425 to 500 at a point 1-1/2" from each end.

## SPIKE MAULS - PLAN NO. 3: (Open Hearth Steel or Alloy\*)

Dimensions, length, striking ends and eye as shown on plan. Brinell 425 to 500, 1/2" back of face of each end. Sample of each lot of twenty dozen or less to be subjected to 1,000 full swinging blows for open hearth steel and 3,000 full swinging blows for alloy steel by continuous hand striking or the mechanical equivalent on a die block of Brinell 400, without undue mushrooming or cracking of the face or edge of mushroom.

## TRACK WRENCHES - PLAN NO. 4: (Open Hearth Steel)

Dimensions as shown on plan. Brinell 375 to 450 at a point 1/2" back from the extreme face of the working end of wrench. One wrench to be tested from each lot of ten dozen or less by applying for one minute a load of 400 lbs at a point distant from the jaw end equal to 95% of the total length of the wrench without any spreading of the jaw or any permanent set in the handle.

## LINING BARS - PLAN NO. 5: (Open Hearth Steel)

Dimensions, length, size and shape of point as shown on plan. Brinell 425 to 500 at a point 1-1/2" from end. One bar to be tested from each lot of ten dozen or less by applying a load of 350 lbs. 12" from the end of the handle, with the point suitably secured 3" from the end, without leaving a permanent set in excess of 1/4".

## RAIL TONGS - PLAN NO. 6: (Open Hearth Steel)

Dimensions as shown on plan.

## TIE TONGS - PLAN NO. 7: (Open Hearth Steel)

Dimensions as shown on plan.

## TIMBER TONGS - PLAN NO. 8: (Open Hearth Steel)

Dimensions as shown on plan.

## SPIKE PULLER - PLAN NO. 9: (Open Hearth Steel)

Dimensions as shown on plan. Brinell 375 to 450, 1/2" from point of jaw. Sample of each lot manufactured to be tested in actual use by pulling a spike with a standard claw bar.

## RAIL FORK - PLAN NO. 10: (Open Hearth Steel)

Dimensions as shown on plan.

\* No Hardness Specifications for Alloy Steel.

## PLAN C-2

## CLAW BAR - PLAN NO.11: (Open Hearth Steel)

Dimensions of claw, depth of heel, length and sectional dimension of handle as shown on plan. Brinell 300-375. One bar from each lot of 20 dozen or less to be tested by placing the claws of the bar  $\frac{1}{2}$ " under the head of a standard track spike, rigidly placed and so located as to hold the bar in a horizontal position while a shock load equivalent to that of a 200 lb. weight falling a distance of one foot is applied to the handle at a point 5" from its end, without the toes showing any cracks or the handle taking any permanent set.

## TRACK ADZE - PLAN NO.12: (Open Hearth or Alloy Steel\*)

Dimensions and detail of eye as shown on plan. Brinell 375 to 450,  $\frac{3}{8}$ " from cutting edge. Test one adze in each lot of twenty dozen or less by subjecting cutting edge to five blows on metal of the same composition as a railroad spike without breakage or serious nicking.

## SLEDGE - PLAN NO.13: (Open Hearth or Alloy Steel\*)

Dimensions and detail of eye as shown on plan. Brinell 425 to 500  $\frac{1}{2}$ " back of face of the sledge. Sample of each lot of twenty dozen or less to be subjected to 1,000 full swinging blows for open hearth steel or 3,000 full swinging blows for alloy steel by continuous hand striking or the mechanical equivalent on a die block of Brinell 400, without undue mushrooming or cracking of the face or edge of mushroom.

## TAMPING BAR - PLANS NOS.14-15: (Open Hearth Steel)

Dimensions as shown on plan. Brinell 425 to 500,  $\frac{1}{2}$ " from working edge or face.

## TRACK CHISEL, DESIGN NO.1 - PLAN NO.16: (Electric or Alloy Steel\*)

Dimensions and detail of eye as shown on plan. Brinell at a point  $\frac{1}{2}$ " back from cutting edge, 477 to 532; at head  $\frac{1}{2}$ " from striking face, 286 to 340. One chisel in each lot of twenty dozen or less to be tested by cutting 100 linear inches in a rail head of Brinell 260 by mechanical or hand striking approximating service conditions, to a depth of  $3/16$ " below original surface; in addition, striking three gouging blows of such intensity as to give for each blow a cut of approximately  $1/16$ " in depth. The chisel point shall stand this test uninjured and the head shall stand up without undue battering.

## TRACK CHISEL, DESIGN NO.2 - PLAN NO.17: (Alloy Steel Only\*)

Dimensions and detail of eye as shown on plan.

## TIE PLUG PUNCH - PLAN NO.18 and ROUND TRACK PUNCH - PLAN NO.19:

Dimensions and detail of eye as shown on plan. Brinell 477 to 532, at a point  $\frac{1}{2}$ " from working end: 286 to 340 at a point  $\frac{1}{2}$ " from striking face.

## TRACK GAGE - PLAN NO.20:

Dimensions as shown on plan. No tolerance allowed in gage distance.

\* No Hardness Specifications for Alloy Steel

## PLAN D-1

A.R.E.A. SPECIFICATIONS FOR HICKORY HANDLES FOR TRACK TOOLS

Handles 24" and longer shall conform to "Grades AA, AW or AR"; handles less than 24" to "Grades SAW or SAR" as set forth in Simplified Practice Recommendation No. 77 of the Bureau of Standards, U. S. Department of Commerce, effective November 1st, 1927.

## DESIGN:

Handles shall conform to the dimensions shown on the plan forming part of this specification, with an allowable variation of one-quarter inch in length, and one-sixteenth inch over or under for all other dimensions. Eyes and dimensions of such handles are in accord with Simplified Practice Recommendation No. 17 - Forged Tools, Bureau of Standards, U.S. Department of Commerce, effective April 1st, 1927.

## PHYSICAL REQUIREMENTS:

Handles shall be smooth, straight and for each type of tool, uniform in size and shape. Handles must be properly seasoned. The grain of the wood must run parallel to the center line of the handle, with an allowable variation of not over one inch in fifty inches. Handles which are warped or twisted shall not be accepted.

## MANUFACTURE:

(a) Handles shall be smoothly finished and waxed.  
(b) Each handle shall be plainly marked for identification by the purchaser, with brand and identification mark, as specified by Simplified Practice Recommendation No. 77. Marking, unless otherwise specified by purchaser, shall be placed near the hand grasp end of handles and letters must not be less than three-eighths inch in height.

## INSPECTION:

(a) Handles will be inspected at points of manufacture, shipment or destination in suitable and convenient places satisfactory to the purchaser.

(b) Inspectors representing the purchaser shall have free entry to the works of the manufacturer at all times while work on the contract of the purchaser is being performed, and shall have all reasonable facilities afforded them, free of cost, to satisfy them that the handles are being supplied in accordance with these specifications.

(c) Inspectors will make a reasonably close examination of each handle and the acceptance or rejection will be based on the inspector's knowledge of the appearance, weight and density required; rings of annual growth will not be counted nor handles weighed by scale unless the inspector's decisions are questioned. Exactness of size and shape will be checked by accurate measurements of handles taken at random.

## DELIVERY:

Accepted handles shall be shipped by the seller in accordance with the instructions in the order covering them; they shall be securely packed in standard packages, each of which shall be marked to show seller's or manufacturer's name and the number, type and grade of the handles contained.

## PLAN D-2

GRADE CLASSIFICATION FOR HANDLES, PLAN NUMBER REFERENCE AND MAXIMUM AND MINIMUM WEIGHTS PER DOZEN

| GRADE "AA"                         | Weights per Dozen |      |
|------------------------------------|-------------------|------|
|                                    | Min.              | Max. |

| Sledge - Plan No. 13               | 15#               | 18#  |
| <br><u>GRADE "AW" or "AR" *</u>    |                   |      |
| Axe - No Plan                      | 17#               | 20#  |
| Adz - Plan No. 12                  | 15#               | 18#  |
| Pick, Clay - Plan No. 1            | 21#               | 26#  |
| Pick, Tamping - Plan No. 2         | 21#               | 26#  |
| <br><u>GRADE "SAW" or "SAR" **</u> |                   |      |
| Track Chisels - Plan Nos. 16 & 17  | 7½#               | 11#  |
| Tie Plug Punch - Plan No. 18       | 7½#               | 11#  |
| Track Punch - Plan No. 19          | 7½#               | 11#  |

\* Note: - Grade "EW" or "BR" may be furnished in lieu of Grade "AW" or "AR" if lower grade of handle is desired.

\*\* Note: - Grade "SEW" or "SER" may be furnished in lieu of Grade "SAW" or "SAR" if a lower grade of handle is desired.

## PLAN D-3

DEFINITION OF GRADES - HICKORY HANDLESTAKEN FROM SIMPLIFIED PRACTICE RECOMMENDATIONS NO. 77 - U.S. DEPARTMENT OF COMMERCEHandles 24" and LongerGRADE AA

Handles having not over 17 rings of annual growth per inch of radius; heavy weight, thrifty growth, all white, free from defects.

GRADES AW AND AR

Handles having not over 22 rings of annual growth per inch of radius, good weight, live growth, free from all defects. Handles of this grade will be supplied in all white wood, the grade symbol being AW; or in red, white, or mixed red and white, for which the symbol will be AR.

GRADES EW AND ER

Handles having not over 27 rings of annual growth per inch of radius, good weight, live growth. These grades permit such handles as have slight iron streaks not exceeding four in number running the entire length of the handle or the equivalent in shorter lengths. To be free from defects except in the first third of the length from the grasp end, or in the eye where is permitted one sound or tight knot or bird peck not over one-fourth inch in diameter or two such knots or bird pecks where combined diameters do not exceed one-fourth inch in diameter or slight deflection of grain. Handles of this grade will be supplied in white wood, the grade symbol being EW; or in red, white, or mixed red and white, for which the symbol will be ER.

Handles Less than 24" in LengthGRADES SAW AND SAR:

Handles having not over 17 rings of annual growth per inch of radius, heavy weight, thrifty growth, free from all defects. Handles of this grade will be supplied in all white wood, the grade symbol being SAW; or in red, white, or mixed red and white, for which the symbol will be SAR.

GRADES SEW AND SER:

Handles of medium weight, live growth, permitting two slight iron streaks the entire length, or their equivalent in shorter streaks. Free from all defects. Handles of this grade will be supplied in all white wood, the grade symbol being SEW; or in red, white, or mixed red and white, for which the symbol will be SER.

## PLAN E

## AREA SPECIFICATION FOR TRACK SHOVELS

(See General Specifications)

## SCOPE AND DESIGN

This specification covers both the welded or riveted type and the solid shank type with either wood, malleable iron or combination wood-metal handle tops. Dimensions shall conform to plans, which are made a part of this specification. A variation of one-half inch more or less from the dimension shown on plan for length of strap or shank and handle will be allowed, but the total variation in length of shovels shall not exceed one inch. Width or length of blade may vary 1/4" over or under.

## MATERIALS

Blades shall be of open hearth, crucible, electric furnace or alloy steel, with Rockwell hardness for carbon steel of 40 to 45.

Carbon steel blades shall be in thickness not less than #13 gauge and alloy blades shall be of not less than #14 gauge U.S. Standard. For welded or riveted type, the straps shall be welded or riveted to the blade.

## HANDLES AND TOPS

Handles shall be made of White Ash and shall conform to "Grade XX" as set forth in Simplified Practice Recommendation No. 76 of the Bureau of Standards, U.S. Department of Commerce. Handles shall be uniform in size and shape, thoroughly air seasoned and smoothly finished. Tops of handles shall be of the design ordered and shall conform to plans that are made a part of this specification.

## TESTS

One shovel from each lot of ten dozens or less shall be selected and metal straps (curved to fit contour of handle) shall be clamped to the upper and lower parts of the handle, after which the shovel shall be placed in a prying position, supported at the end of the blade by clamps and shall be capable of sustaining a load of 800 lbs. suspended from the end for a period of two minutes without showing any permanent set, fracture or distortion.

Alloy steel shovels which have been given a heat treatment to insure uniformity in hardness shall be subjected to a shock test to insure against brittleness. The test shall be made by forcibly striking the blade of the shovel with a hand hammer at several places when placed on an anvil.

## PLAN F

## AREA SPECIFICATIONS FOR BALLAST FORKS

(See General Specifications)

## DESIGN

Dimensions of forks shall conform to plan which is made a part of this specification.

## MATERIALS

Forks shall be made of high grade Open Hearth Steel.

Times of forks shall show Brinell hardness of 259 to 331.

## HANDLES

Handles shall be made of White Ash and shall conform to "Grade XX" as set forth in Simplified Practice Recommendation No. 76 of the Bureau of Standards, U. S. Department of Commerce. Handles shall be straight, uniform in size and shape, thoroughly seasoned and smoothly finished.

Permissible variation in overall length of tool shall not exceed 1/2"

## Appendix E

### (4) PLANS FOR SWITCHES, FROGS, CROSSINGS, SLIP SWITCHES, ETC.

O. F. Harting, Chairman, Sub-Committee; C. A. Alden, E. W. Caruthers, J. W. DeMoyer, L. W. DesLauriers, J. A. Ellis, W. G. Hulbert, T. T. Irving, A. A. Johnson, F. H. Masters, J. V. Neubert, G. A. Peabody, O. C. Rehfuess, E. M. T. Ryder, G. J. Slibeck, G. L. G. Smith, H. C. Stiff, J. B. Strong, E. D. Swift, H. N. West, J. G. Wishart, M. J. T. Zeeman.

The plan presented in this Appendix was prepared in conference with the Standardization Committee of the Manganese Track Society.

The Committee presents for adoption as recommended practice Plan 505, which is a written plan consisting of specifications for adjustable guard rail clamps. Guard rail clamps are now in use on a number of large railroad systems, and this plan was prepared to enable railroads to obtain guard rail clamps of a more suitable and uniform design.

The Committee reports progress on a number of other assignments.

## Conclusion

The Committee recommends that Plan 505—A.R.E.A. Specifications for Adjustable Guard Rail Clamps, included in the revised Portfolio of Trackwork Plans, be adopted as recommended practice and printed in the Manual.

## Appendix F

### (5) TRACK CONSTRUCTION IN PAVED STREETS

E. W. Caruthers, Chairman, Sub-Committee; C. A. Alden, W. G. Brown, J. E. Deckert, J. W. DeMoyer, F. W. Gardiner, C. R. Harding, O. F. Harting, W. G. Hulbert, W. A. Murray, J. B. Myers, G. A. Peabody, E. M. T. Ryder, H. C. Stiff.

The Committee confined its work this year to a review of its material appearing in the Manual, and revisions recommended have been handled under Appendix A.

The Committee reports progress on a number of other assignments.

## Appendix G

### (6) CORROSION OF RAIL AND FASTENINGS IN TUNNELS

W. H. Bettis, Chairman, Sub-Committee; C. J. Geyer, R. W. E. Bowler, J. de N. Macomb, J. V. Neubert, G. L. G. Smith, H. N. West.

The Committee reports progress. Information on this subject is not developed sufficiently to warrant a report this year.

## Appendix H

## (7) GAGE OF TRACK AND ELEVATION OF CURVES WITH REFERENCE TO THE USE OF ROLLER BEARINGS ON RAILROAD EQUIPMENT

C. W. Breed, Chairman, Sub-Committee; J. E. Hogan, C. M. McVay, C. R. Strattman, T. P. Warren.

The elevation of curves must be governed primarily by the speed of trains passing over them. If the use of roller bearings because of mechanical construction were a controlling factor of the speed of trains in which they might be used, to that extent might they be an element in selecting the proper elevations of curves over which the train passed.

In order to obtain accurate information relative to the possible limits in the use of roller bearings on curves at any desired speed of operation, letters of inquiry were addressed to the large manufacturers of roller bearings which elicited the following replies:

**Fafnir Bearings Incorporated, New Britain, Connecticut.**—"We have been over this subject carefully with our engineering department, and beg to advise that the problem, as far as it relates to the use of our roller bearings, the same standards would apply as on the sleeve bearings. In other words, we do not make a rigid set up as is common in some types on the market. Our application carries the same float as is common with sleeve type bearings, and the same clearance between the end of the axle and the thrust block."

**Hyatt Bearing Division, General Motors Corporation, Newark, New Jersey.**—"From the standpoint of Hyatt roller bearing applications to rolling stock, we do not see that there are any problems involved with a Hyatt application which are not present with the brass bearing application. The Hyatt type axle is allowed a lateral freedom similar to that allowed with the brass bearing axle. The total lateral clearance for a Hyatt axle is from  $\frac{3}{8}$  in. to  $\frac{1}{2}$  in. which will compare with a similar clearance for a new installation of brass bearings. We are, therefore, of the opinion that any standards, which are affecting track elevation and gage, will be equally applicable to either brass bearings or Hyatt roller bearing journals."

**Shafer Bearing Corporation, 6501-99 W. Grand Ave., Chicago.**—"With Shafer roller bearing used in railroad equipment, fitted in American Steel Foundry units, we are glad to advise that in these units the axle shaft is stationary and is carried in regular journal boxes, with no change in lateral clearance. For this reason their action on curves will be identically the same as the standard plain bearings."

**S K F Industries, Inc., 40 East 34th Street, New York.**—"We have been using the S K F Spherical Roller Bearing for journal applications for more than ten years and have had extensive experience with practically all types of steam railway equipment except freight cars. We have done some work with freight cars, but very little in comparison to that represented by the use of these bearings on passenger train equipment and locomotives. The questions raised in your letter are not the ones which we have had occasion to study or investigate thoroughly. Up to the present time, we have seen nothing to indicate that any special requirements for gage of track or elevation of the outer rail on curves are necessary when the spherical journal bearing is used."

**The Timken Roller Bearing Company, Canton, Ohio.**—"On the subject of track gage and elevation of curves, we are of the opinion that no changes should be made in the tables because of roller bearings. Any new conditions, which may arise from the use of roller bearings, should properly be confined to the rolling stock so equipped. The formula for elevation of the outer rail on a curve is a function of speed and degree of curvature only. The condition of rolling stock does not enter in except as it may affect speed. We have noted a marked tendency to introduce roller bearings on high-speed equipment. As the modern trend is toward higher speeds, some changes in track may be made, but no changes in the tables are involved. Regarding lateral play at journal boxes, we have found it possible to obtain any desired amount of movement between box and frame as designed for Timken bearings. Wheel gages can also be varied. These possibilities are fortunate, as the table for gages and flangeways always contains a large number of factors and should not be made more complicated."

### Conclusion

There is no different problem in the selection of the proper elevation for curves over which it is desired to operate railway equipment using roller bearings than is present if equipment is supplied with ordinary bearings.

This report is submitted as information.

### Appendix I

#### (8) EFFECT OF EXISTING MATERIALS IN TRACK ON DESIGN OF TIE PLATES AND PUNCHING THEREOF, TOGETHER WITH INTERRELATION OF SLOTTING OF JOINT BARS AND SIZE OF TRACK SPIKES

J. de N. Macomb, Chairman, Sub-Committee; W. H. B. Bevan, R. W. E. Bowler, H. R. Clarke, L. W. Deslauriers, F. W. Gardiner, C. R. Strattman.

On account of the preparation of designs for Tie Plates by the Track Committee and for Joint Bars by the Rail Committee, it is recommended that this subject be discontinued.

### Appendix I-1

#### (8-A) DESIGN OF TIE PLATES FOR RE RAIL SECTIONS

J. de N. Macomb, Chairman, Sub-Committee; W. G. Arn, W. H. Bettis, W. H. B. Bevan, M. D. Bowen, R. W. E. Bowler, E. W. Caruthers, H. R. Clarke, L. W. Deslauriers, J. A. Ellis, F. W. Gardiner, C. J. Geyer, C. R. Harding, F. W. Hillman, A. A. Johnson, J. B. Myers, J. V. Neubert, E. M. T. Ryder, J. R. Scatterday, G. L. G. Smith, G. M. Strachan, C. R. Strattman, J. R. Watt, J. G. Wishart.

At the meeting of the Track Committee on September 21, 1933, the subject "Plans for Standard Tie Plates" was assigned.

Standard drawings of most of the larger railroads represented in the Association covering track materials were available to the Sub-Committee. From these standard drawings tabulations were prepared, showing the characteristics of the tie plates in use by these railroads with rails of various weights and sections. Studies were made of these tabulations, keeping in mind the trend toward more sturdy construction in railroad track, as a result of which the tie plate plans shown in Fig. 2 to 8, inclusive, were prepared, their principal characteristics and uses being summarized in Fig. 1.

Fig. 1 to 8 inclusive, attached hereto, together with the two "Notes", 1 and 2, are presented for adoption as recommended practice.

### Conclusions

The Committee recommends:

That the material shown under the headings "Table of Dimensions for Tie Plates" and "Data for Designing Tie Plates" on page 251 of the 1929 Manual be withdrawn.

That plans, Fig. 1 to 8, inclusive, submitted herewith, together with Notes 1 and 2, following, be adopted as recommended practice and printed in the Manual.

NOTE 1.—Where a railroad's existing Standard Tie Plate is canted approximately 1 in 20, or has no cant (flat), A.R.E.A. standard design may be modified to correspond therewith, for use with rails having the same base width.

NOTE 2.—Where existing standard spacing of spike holes, parallel to shoulder of tie plate, used with same width of rail base by any railroad, is not in accordance with A.R.E.A. standard, such existing spacing may be substituted.

All A.R.E.A. Standard Tie Plates to be 7 $\frac{1}{2}$  inches wide.

Where existing standard spacing of spike holes, parallel to shoulder of the plate, used with same width of rail base by any railroad, is not in accordance with A.R.E.A. standard, such existing spacing may be substituted.

All A.R.E.A. Standard Tie Plates to be cant ed approximately 1 in 40.

Where a railroad's existing Standard Tie Plate is cant ed approximately 1 in 20, or has no cant ("flat"), A.R.E.A. standard design may be modified to correspond therewith, for use with rails having the same base width.

On account of the urgent need for the tie plate standards due particularly to the recent adoption of new rail sections, the Track Committee is submitting these plans for adoption as recommended practice rather than as information. With this in view, the Committee will welcome suggestions and criticisms.

## Appendix J

### (9) PRACTICABILITY OF USING REFLEX UNITS FOR SWITCH LAMPS AND TARGETS

J. B. Myers, Chairman, Sub-Committee; W. H. Bettis, J. J. Desmond, F. J. Jerome, H. D. Knecht, J. C. Mock, J. B. Strong.

The subject this year was a reassignment from the previous year, and it was thought that information would be available from which definite recommendations could be made. In the 1932 report, twenty railroads had a limited number of Reflex Units in test, and three had an appreciable number in service and considered them satisfactory.

Our investigation this year develops the fact that many of the roads who reported in 1932 as having Reflex Units in test, have removed them. account of discontinuing the use of Switch Lamps in the Automatic Signal territory.

A few of the roads report that they are continuing their tests, but have no information to report this year.

Two roads reported they had installed additional units for test. The two roads who have a large number in service and who appear to have standardized on the Reflex Unit, report they expect to continue replacing lighted switch lamps with the Reflex Lens as rapidly as conditions permit.

None of the roads questioned has considered the use of reflex units outlining the banner or target of switch stands, thereby eliminating the switch lamp or its substitute.

## Conclusion

Recommend that this report be received as information.

## Appendix K

### (10) SELECTIVE WELDING UP AT JOINTS, INSTEAD OF WELDING OUT OF FACE

F. W. Hillman, Chairman, Sub-Committee; W. G. Arn, M. D. Bowen, J. A. Ellis, C. J. Rist, G. L. Sitton.

Subject No. 13 added to Track Committee's work precludes investigation of subjects suggested in conclusion of report of Sub-Committee 10 appearing on page 518 of Vol. 34, 1933 Proceedings, and limits investigation of this Committee to determining when selective or out of face welding shall be done. This phase was completely reported on last year. Therefore it is now the recommendation of Sub-Committee 10 that report appearing on page 515, Vol. 34 of 1933 Proceedings be accepted as information and subject dropped until some future date when greater progress in welding of rail at joints has been made and developments warrant further study of the subjects.

## Appendix L

## (11) DESIRABLE TIGHTNESS OF TRACK JOINTS AND EFFECT UPON THE LIFE OF RAILS AND JOINTS OF OVERTIGHT JOINTS; OF LOOSE JOINTS

W. J. Harris, Chairman, Sub-Committee; J. J. Desmond, J. de N. Macomb, I. H. Schram, Theo. Speiden Jr., T. P. Warren, M. J. T. Zeeman.

The following questionnaire was sent to all railroads represented in the A.R.E.A. to ascertain their practice, experience and opinions on this subject.

1. What is "desirable tightness" of track joints to obtain maximum life of rail and joints?
2. How do you determine "desirable tightness" of track joints?
3. What effect has overtight joints on rail, such as:
  - (a) Battered ends?
  - (b) Wear on fishing surfaces?
  - (c) Breakage through bolt holes, etc.?
4. What effect have loose joints on rail, such as:
  - (a) Battered ends?
  - (b) Wear of fishing surfaces?
  - (c) Breakage through bolt holes, etc.?
5. To what extent is the life of rail shortened by:
  - (a) Overtight joints?
  - (b) Loose joints?
6. To what extent is the life of joints shortened by:
  - (a) Overtight joints?
  - (b) Loose joints?
7. Does the use of spring washers or joint springs have any effect on overtightening?

Answers were received from thirty-five railroads. These answers are such that a brief summary cannot be made and a complete copy of them would be quite voluminous.

Opinions given for "desirable tightness" vary from 7,000 lb. to 20,000 lb. per bolt.

The majority opinion, however, as given in the answers to the questionnaire is summarized in the following:

## Conclusions

## 1. DESIRABLE TIGHTNESS OF TRACK JOINTS

Desirable tightness of track joints is that degree of tightness in which the bolts are kept as tight as possible, and still permit the rails to move uniformly with contraction and expansion. This can be obtained by the average trackman exerting his full strength on a forty-two to a forty-eight inch wrench, depending on the size of bolt, kind of threads and condition of bolt, and by frequent inspection and careful maintenance.

## 2. EFFECT UPON THE LIFE OF RAILS AND JOINTS OF OVERTIGHT JOINTS

With overtight joints there is a tendency for rails to kink and for batter to be excessive at the wider joint openings, due to distribution of expansion not being uniform. This, however, will have little effect generally upon the life of the rail as a whole. The life of the joints will be increased because the tightness will tend to reduce to a minimum the movement of rails and joint assembly, thereby reducing wear.

## 3. EFFECT UPON THE LIFE OF RAILS AND JOINTS OF LOOSE JOINTS

Loose joints cause excessive batter of rail ends; cause surface bent rails; cause abnormal wear on both rails and joints, thereby materially shortening the life of both; and are responsible for a very large portion of the labor cost of maintenance.

The Committee offers this report as information and recommends that the subject be discontinued.

Recapitulation of Answers Received from A.R.E.A. Questionnaire

## (12) RECLAMATION OF SERVICEABLE MATERIALS FROM SCRAP AND RETIRED MAINTENANCE OF WAY AND STRUCTURE MACHINES, TOOLS AND APPLIANCES

J. R. Watt, Chairman, Sub-Committee; T. T. Irving, W. A. Murray, G. A. Peabody, W. L. Roller, G. L. Sitton, J. G. Wishart.

The Committee reports progress. Information on this subject is not developed sufficiently to warrant a report this year.

## Appendix N

## (13) METHODS OF RECONDITIONING OF RAIL ENDS, FASTENINGS, FROGS AND SWITCHES IN TRACK

G. M. Strachan, Chairman, Sub-Committee; M. D. Bowen, F. W. Hillman, H. D. Knecht, O. C. Reh fuss, C. J. Rist, G. J. Slibeck.

There is submitted herewith in tabular form replies to questionnaire sent out by the Sub-Committee. The twenty-four railroads reporting are among the largest in the United States and Canada and represent all sections of the country; therefore, the information developed may be taken as fairly representative of the present trend of track welding.

The earliest date recorded for oxwelding of rail ends was 1917, while one road reports starting work by this process as late as 1928. The first electric-arc rail end welding is given as 1926. In the early years, all the work done by the oxy-acetylene process was by company forces using flatter for finishing the welds. The application of electric-arc welding to rail ends brought out a grinding machine for the finishing and this grinding restores the rail end more uniformly to original contour at little, if any, increased cost. Its use, therefore, has spread to oxwelding. A grinding machine, of which there are several designs on the market, can usually keep pace with the double arc electric welding unit or with a gang of five or six oxy-acetylene welders.

A study of the replies as regarding costs reported for the building up of rail ends on various railroads indicates considerable variation, cost depending primarily on the amount of batter and the length of weld, also, whether or not the rail ends are built up "out-of-face" or spot welded. Differences in accounting for labor, material and overhead are noted in various replies submitted, the majority of roads basing their costs on unit rate per joint, others on per inch of weld, while some compare costs on per pound of metal deposited. So many variables enter into welding work that cost figures from one road cannot be compared to those obtained from another road unless complete history is available.

The amount of batter determining when welding should be done varies from  $\frac{1}{2}$  to  $\frac{1}{8}$ -inch. However, the majority of railroads indicate that on high speed main tracks the rail ends with an average batter of  $\frac{3}{64}$ -inch require welding "out-of-face." Replies further indicate that either from batter, chipping or a combination of the two, rail ends of track carrying annually ten million tons or better require building up after a four or five-year life, and that these rail ends, after being rebuilt, give a similar average service life before requiring a second rebuilding. That this handling of rail ends is economical is indicated by replies to Question 6, and as stated in summary, the rebuilding of rail

ends increases the life of main track rail in first position from 50 per cent to 100 per cent. By either method of rebuilding first-class results can be secured. Failures reported are negligible, being only a small fraction of one per cent.

Reports indicate that roads using oxy-acetylene for the reconditioning of their rail ends, frogs and switches, handle this work by company forces. Of the roads using electric arc, some handle the work by contract, others by company forces.

### Conclusion

Your Committee believes that this assignment is a very important subject, and recommends that this report be received as information.

The Committee reports progress. Information on this subject is not developed sufficiently to warrant a report this year.

### Appendix P

#### (15) DAMAGE TO TRACK AND DEVICES DUE TO BRINE DRIPPINGS FROM REFRIGERATOR CARS

W. G. Arn, Chairman, Sub-Committee; W. J. Harris, A. A. Johnson, G. M. Strachan, J. G. Wishart.

The Sub-Committee from this Association working with the Mechanical Division Sub-Committee, joined in the following report;

#### CONCLUSIONS AND RECOMMENDATIONS OF JOINT SUB-COMMITTEE ON DAMAGE TO TRACK AND DEVICES DUE TO BRINE DRIPPINGS FROM REFRIGERATOR CARS

"Your Committee has analyzed the data gathered by the former committee appointed in 1928. In addition, another field inspection has been made for the purpose of disclosing conditions obtaining at this time on refrigerator cars equipped with brine tanks. This reveals that out of 504 brine tank cars inspected, 32.9 per cent were found defective, while in 1928, when a similar inspection was made, 61.3 per cent were found defective. This shows a marked improvement over conditions existing.

"The Committee believes, however, that there is still room for further improvement, and in order that this may be brought about, it is suggested that, so far as may be practicable, the mechanical inspection department be authorized to make periodic inspection of brine tank cars at loading stations or other suitable locations, the results of these inspections to be transmitted currently to the Secretary, Mechanical Division, and that he, in turn, notify owners of any cars found having brine tanks or fittings in defective condition together with the station involved, with the suggestion that the necessary corrective measures be immediately taken.

"As to open bunker cars, the committee has given consideration to the practicality of equipping these cars with suitable containers for retaining brine between icing stations as well as the cost of application. It is estimated that it would cost \$282.00 per car to install containers. The committee has prepared several designs of tanks but is unable to conceive of any constructions which would be economical or entirely practicable. On the basis proposed, it would mean a total expenditure of \$39,198,000.00.

"To equip the cars with brine containers would seriously impair their carrying capacity as the containers themselves would weigh approximately 3000-lb. and, when filled, would weigh approximately 12,500-lb. This would essentially reduce the load carrying capacity of a 40-ton capacity car to that of a 30-ton car, and could be overcome only by the application of higher capacity trucks at an estimated cost of \$400.00 per car. Such procedure would, however, affect the nominal capacity of the equipment and also affect the tariff structure. The estimated cost of installing brine containers and changing trucks on existing 40 and 50-ton nominal capacity cars would be:

$$139,000 \times \$282.00 = \$39,198,000.00$$

$$103,200 \times \$400.00 = \$41,280,000.00$$

$$\hline \$80,478,000.00$$

"The foregoing does not take into consideration the cost of tank renewals, repairs, inspection and cleaning, which is estimated would amount to \$100.00 per car, per year, or a total of \$13,900,000.00, nor the cost of changing trucks on 35,800 30-ton cars. Neither is included the additional cost of hauling the excess weight, the additional maintenance cost on account of higher capacity trucks, if applied, interest on the increased capital investment, nor the possibility of damage to cars and lading due to clogging or freezing of pipe fittings and tanks.

"The Sub-Committee, Engineering Division, has tabulated estimates received from railroads reporting damages to tracks, bridges, and signals, through brine drippings from refrigerator cars which indicate that an annual excess maintenance expense of \$2,350,000.00 is incurred from this cause on approximately 17,938 miles of main tracks. This figure includes both the cost of damage to material and of protection against such damage.

"On the basis of this amount of annual damage to tracks, bridges and signals, the capital expenditure which would be justified at 5 per cent interest is \$42,000,000.00 while the estimated cost of equipping open bunker type cars only is estimated at \$39,000,000.00 to which should be added such additional sums required for changing to higher capacity trucks, maintenance, etc. Clearly, this expense is not justified for the saving that might be made especially as the open bunker type car contributes only a part, and possibly a minor part, of the damage from brine, the balance coming from the cars equipped with brine retaining devices due to defects in this equipment.

### Recommendations

"A higher degree of maintenance of tanks and fittings on existing brine tank equipment and better protection of tracks, bridges and signals against brine drippings. Under existing circumstances this seems the most economical and practical procedure."

It is recommended that the subject be dropped, at least until such time as there are developments which would make it worthwhile to revive this subject.

### *To the American Railway Engineering Association:*

Your Committee on Masonry respectfully presents herewith reports covering the following subjects:

- (2) Specifications and principles of design of plain and reinforced concrete (Appendix A).
- (3) Progress in the science and art of concrete manufacture (Appendix B).
- (5) Specifications for foundations (Appendix C).
- (6) Methods and practices of lining and relining tunnels (Appendix D).
- (7) Specifications for concrete to be applied by propelling machines of the type of the "cement gun", (Appendix E).
- (8) Design of expansion joints involving masonry structures (Appendix F).

The Committee reports progress on

- (1) Revision of Manual;
- (4) Contact with Joint Committee on Standard Specifications for Concrete and Reinforced Concrete;
- (9) Study Specifications for overhead highway bridges as prepared by the Association of State Highway Officials.

### **Action Recommended**

- (1) That Section 1, Appendix A, be approved for printing in the Manual as Recommended Practice.
- (2) That the definitions of Appendix C, be approved for printing in the Manual.
- (3) That Section 2 of Appendix A, Appendix B, remainder of C, and Appendices D, E and F, be received as information.

Respectfully submitted,

THE COMMITTEE ON MASONRY,  
MEYER MIRSCHTHAL, *Chairman*.

**George E. Tebbetts**

The Committee was greatly shocked by the announcement of the sudden death of George E. Tebbetts, Engineer of Structures, Chicago Rapid Transit Company. Mr. Tebbetts died December 13th, following an operation. His loss will be deeply felt by both the Committee and the Association.

---

Bulletin 364, February, 1934.

## Appendix A

## (2) SPECIFICATIONS AND PRINCIPLES OF DESIGN OF PLAIN AND REINFORCED CONCRETE

A. N. Laird, Chairman, Sub-Committee; J. F. Leonard, F. E. Bates, T. L. Condon, Hardy Cross, Theo. Doll, A. C. Irwin, A. R. Ketterson, C. P. Schantz, L. W. Skov, A. W. Smith, I. F. Stern, Jamison Vawter, C. C. Williams.

Your Committee reports progress on the subject of Reinforced Concrete Arches and presents the following report as information and for suggestions in continuation of the subject reported on last year. It is the intention during the coming year to review the subject-matter contained in this report together with that previously submitted and present it at the next convention in the form of Specifications for the Design and Construction of Reinforced Concrete Arches for Railroad Loadings, for adoption by the Association as recommended practice.

## SECTION 2

## (I) REINFORCED CONCRETE TRESTLE DESIGN—E-60 LOADING

FIG. 1.—Design for Single Bent.

Double bents to be used every 5<sup>th</sup> bent when the height (Base of rail to top of ground) is more than 20 feet.  
Cap extension between slabs to be set after placement of slabs if necessary.

FIG. 2.—Design for Double Bent Reinforced Concrete Trestle.

FIG. 3.—Design for End Bent.

FIG. 4.—Design for Slab.

## Design B

The drawing consists of two views: a Top View and an End View.

**Top View:** Shows a rectangular bracket with a width of 2' x 4" and a length of 9'-0". It features a 3' x 3' x 1/8" L-shaped section and a 4' x 12" Planks section. The bracket is supported by a 2' x 4" track. The drawing includes a 1/8" Recess for bracket and a 1/8" Recess for bracket.

**End View:** Shows the bracket's profile with a height of 8'-1". It includes a 5' x 3' x 1/8" L-shaped section and a 5' x 3' x 1/8" L-shaped section. The bracket is supported by a 2' x 4" track. The drawing includes a 1/8" Recess for bracket and a 1/8" Recess for bracket.

**Labels:** The drawing is labeled with dimensions and materials: 2' x 4" track, 3' x 3' x 1/8" L, 4' x 12" Planks, 8'-1", 5' x 3' x 1/8" L, 1/8" Recess for bracket, and 1/8" Recess for bracket.

FIG. 7.—Slabs and Bent for Multiple Track.

(II) DESIGN AND CONSTRUCTION OF REINFORCED CONCRETE  
ARCHES (Continued)

## 8. Piers and Abutments

Arch piers and abutments shall be designed to resist the forces resulting from dead load, combined with the most unfavorable condition of live loading, together with temperature and shrinkage distortions and from distortions of the foundation beds. The stresses at critical sections between springing line and footing, including those resulting from the effect of unbalanced thrusts from adjoining arch rings or ribs shall be carefully analyzed. The bearing areas shall be proportioned so that the allowable pressures on the foundation beds shall not be exceeded and that settlement, if any, shall be uniform.

The stability of arch piers shall also be investigated for conditions of loading during the construction period, including the effect of unbalanced thrust from arch rings or ribs, and distortion due to temperature changes and shrinkage. In long structures, intermediate piers at intervals shall for construction purposes be designed as abutment piers to withstand such forces from one side of the pier only, without assuming support on the other side. Such abutment piers shall be clearly designated on the plan.

In the design of arch abutments the change in distribution of pressure to the foundation beds resulting from the application of earth pressure against the back of the abutment, with and without the addition of live load surcharge, in accordance with

usual practice in the design of abutments, shall also be investigated, and the allowable pressures on the foundation beds shall not be exceeded under such conditions of loadings. In case of rotation of the arch abutment as a result of unequal distribution of pressure on the foundation beds, or in case horizontal movement as a result of the horizontal component of the thrust on the abutment appears possible, the effect of such movement on the arch ring or ribs should be investigated. The form of abutment shall be selected such that the resultant line of pressure shall preferably lie within the middle third of the base and as close to the center of the base as practicable. Insofar as practicable, the forces tending to produce sliding of the abutment shall be resisted, in combination with the vertical components of the dead load and arch thrust, by direct bearing on the foundation. Where this is impracticable, the frictional resistance of the footing slab on the foundation and the bearing resistance of abutting undisturbed material against back of abutment may be considered as assisting the stability against sliding. Additional resistance may be provided, if required, by the construction of a key or drop wall extending below the footing slab, in direct contact with undisturbed foundation material.\* Where permanent cofferdam construction encloses the foundation, this may be considered as increasing the lateral bearing area against undisturbed material for resistance to sliding. Where the foundation rests on permanent piling or caisson construction, the horizontal component of batter piles or caissons may be considered in determining the resistance to sliding. Where the angle of the arch axis is skewed with the face of the abutment or pier, adequate provision shall be made for the transmission of the transverse component of the arch thrust to the pier of abutment proper, in addition to the longitudinal reinforcement required at the skew back.

### (III) DETAILS OF DESIGN

#### 1. General

The design drawings shall be prepared in such detail as to clearly indicate all important elements of the construction, dimensions, spacing and size of reinforcing bars, construction and expansion joints, waterproofing, drainage and maximum foundation pressures or pile loads.

#### 2. Spandrel Construction

##### (a) OPEN SPANDREL TYPE

In open spandrel construction, the deck slabs and beams shall be considered as continuous members between expansion joints, and shall be reinforced accordingly. Transverse bars shall be provided in the bottom of deck slabs for the full length thereof, and in the top of the slabs over supports between quarter points of adjoining spans.

Flat slab spandrel construction shall conform to the requirements of the A.R.E.A. standard specifications therefor.

Spandrel arches shall be reinforced longitudinally parallel with both extrados and intrados using not less than 0.2 per cent of the arch section at the crown. Transverse reinforcement shall be provided for arch rings.

Spandrel columns shall conform to the A.R.E.A. standard specifications for Columns. Transverse walls shall be treated as columns with lateral ties. They shall be reinforced parallel with both faces, both horizontally and vertically.

\* It is recommended that in such cases, not more than 50 per cent of the estimated frictional resistance between the footing slab and foundation, together with not more than 50 per cent of the allowable foundation bearing pressure per square foot, for equivalent material, be used in computing the resistance to sliding due to key or drop wall and to abutting undisturbed material against back of abutment.

### (b) FILLED SPANDREL TYPE

In filled spandrel construction the spandrel walls may be of gravity, cantilever or counterfort design or tied back with transverse walls. Counterfort or cantilever construction shall be proportioned and reinforced to minimize transmission of torsional stresses to outer section of the arch ring. The face of the spandrel walls shall be reinforced in two directions for temperature.

### 3. Arch Ring and Ribs

Arch rings and ribs shall be reinforced in planes parallel to both intrados and extrados. Longitudinal reinforcement shall be provided as required by the arch stresses but not less than 0.2 per cent of the area of the crown section shall be used both top and bottom. Transverse reinforcement shall be provided for arch rings.\*

Bearing seats for columns and transverse walls over arch rings or ribs shall be horizontal with suitable dowels to anchor to the spandrel construction. The spandrel wall reinforcement in filled type arches shall preferably extend into the arch ring with adequate anchorage to develop the strength of the bars in bond.

### 4. Abutments, Piers and Footing Slabs

Abutments, piers, and footing slabs shall conform to the requirements of Sections 127 to 135, inc., of the standard specifications of the A.R.E.A. therefor.

### 5. Construction and Expansion Joints

The requirements of the A.R.E.A. standard specifications, Sections 57 to 63, inc., covering construction and expansion joints shall be complied with.

Construction joints required to transmit stress shall be keyed and reinforced across the joint. Longitudinal construction joints in arch rings shall be vertical, and parallel to the longitudinal axis of the structure. Transverse joints in arch rings or ribs shall be radial. Horizontal construction joints shall not be permitted in arch rings or ribs and shall be avoided where possible in other portions of the construction except where required by construction limitations and to permit proper shrinkage of the concrete in such members as columns. Such construction joints shall be clearly designated on the plans.

In skew arch construction the joints at the springing line may consist of a series of stepped joints, each perpendicular to the line or thrust of the arch ring or ribs, or in the case of solid ring construction, may be on the line of the face of the pier or abutment, but provision shall be made in such cases by special anchorage, keys and reinforcing to transmit the transverse component of the arch thrust to the piers and abutments.

Vertical expansion joints shall be provided in open spandrel construction at or near the face of piers and abutments and, depending on the length and shape of the arch span, at points of the span. In longer structures, these may be required at intermediate intervals. In filled spandrel construction, the expansion joints in the spandrel walls shall be provided as required for open spandrel construction and in addition shall be spaced not more than 30 feet apart.

### 6. Drainage

Adequate drainage shall be provided where water may collect. Nominally horizontal surfaces exposed to moisture shall be sloped for drainage. Deck slabs shall be given a slope preferably  $\frac{1}{4}$ -in. per foot and not less than  $\frac{1}{8}$ -in. per foot, if practicable,

\* Transverse bars  $\frac{5}{8}$  in. round spaced 18 in. centers or the equivalent thereof placed in both top and bottom of arch ring outside of the longitudinal bars are recommended as a minimum requirement.

away from expansion and construction joints. A raised lip shall be constructed at such joints to prevent impounded water from overflowing into the joint. Suitable ballast guards and flashing shall be provided at all deck drainage openings with lead-out pipes to prevent water falling on surfaces of the structure. Weep holes or pipe drains shall be provided for drainage of backs of abutments to prevent impounding of the water. Pipe openings shall be provided through all transverse walls or other members which would interfere with the normal flow of water, in accordance with the drainage layout. Provision shall be made for ultimate disposal of the water in accordance with the local requirements of the site.

## 7. Waterproofing

The deck surface of open spandrel slabs or arches and the extrados of filled arches shall be waterproofed using a membrane type of waterproofing and a protective covering in accordance with the standard specifications therefor of the A.R.E.A. Backs of abutments above the footing slab shall be damp proofed. All construction and expansion joints exposed to water, or in contact with soil or filling materials, including ballast, shall be waterproofed with a membrane type of waterproofing as specified for deck construction and shall preferably have a sheet metal water stop of non-corrosive material equally embedded in both sides of the joint for the full length thereof. Where the joint is designed for expansion this sheet metal water stop shall be looped to provide for the movement. Suitable keyways shall be constructed at construction and expansion joints where the details will permit except where one surface is designed to slide upon the other.

## (IV) CONSTRUCTION

### 1. General

The General Specifications for Plain and Reinforced Concrete of the A.R.E.A. shall apply hereto insofar as consistent, subject to such modifications as provided herein, or by the detailed plans which shall be rigidly adhered to.

The Contractor shall submit a detailed construction schedule for approval by the Engineer.

### 2. Arch Ring and Rib

#### (a) CENTERING

The contractor shall submit designs for the arch centering for approval by the Engineer. Arch centering shall be of rigid construction conforming to the shape of the arch ring or ribs, with adequate foundation bearing area, piling or other suitable construction to sustain the dead load of the concrete while it is being placed, construction equipment, spandrel forms, etc. It shall be braced in both longitudinal and transverse directions and shall be constructed with oak wedges, or sand boxes or other devices for adjusting the shape of the arch ring and for striking the centering gradually and uniformly after the concrete has cured sufficiently. Allowance shall be made in the form and elevation of the arch centering for the dead load deflection of the arch. When local conditions such as waterway, roadway, or other conditions demand that specific clearances be provided under the structure during construction, such as to require that a long span be used for centering, allowance shall be made when setting the forms for the deflection of such span due to its own dead load and to the dead weight of the wet concrete to be supported, and suitable means shall be provided for adjusting the forms to their proper contour. Arch centering shall not be struck or removed until the concrete has sufficiently cured to maintain its own weight and that of the spandrel construction.

### (b) CONCRETING METHODS

The concrete shall be placed for each rib or ring or subdivision thereof in a symmetrical order with relation to the arch piers to minimize springing or distortion of the arch centering, and unequal loading of arch piers. The sections to be placed in one day shall consist either of longitudinal strips for the full length of the arch span conforming in width to the established location of construction joints or voussoir sections, of such length as designated on the plans leaving open joints with suitable dowels, and keys to engage later sections. The schedule of placing concrete shall be submitted by the contractor for approval by the Engineer in accordance with the requirements of the drawings.

### 3. Spandrel Construction

The concrete portion of the spandrel construction shall not be placed until concrete of arch ring or ribs has sufficiently cured to withstand the super-imposed load and until arch centering has been struck. In open spandrel construction concrete for columns and transverse walls shall be placed to the underside of the floor slab or to the springing line of spandrel arches and permitted to remain for a period directed by the Engineer before proceeding with the placement of the balance of concrete of the spandrel construction. Centering and bracing for spandrel construction shall remain in place until slab or spandrel arch concrete is placed.

Filling materials for placement over arch rings and behind arch abutments shall be of porous structure which will permit rapid drainage. Filling materials shall be placed uniformly and symmetrically in horizontal layers, and properly compacted. In filled spandrel construction, the filling material shall be placed uniformly for each span commencing at piers and working toward the crown. In multiple span structures this filling operation shall preferably be carried on uniformly for all spans between abutment piers at substantially the same time. Puddling of filling material over the arch ring will not be permitted.

## Appendix B

### (3) PROGRESS IN THE SCIENCE AND ART OF CONCRETE MANUFACTURE

L. W. Walter, Chairman, Sub-Committee; Maurice Coburn, L. V. Haegert, W. K. Hatt, A. C. Irwin, J. A. Lahmer, O. V. Parsons, W. M. Ray, D. A. Ruhl, D. B. Rush, W. K. Wyatt.

#### SECTION I

#### VIBRATION IN PLACEMENT OF CONCRETE

The first important application of vibration to the placement of concrete was in connection with the construction of concrete ships during the World War. Successful placement of concrete in the heavily reinforced thin walls and structural parts of these ships would have been well nigh impossible by any other means. Vibration in these cases was accomplished by applying air hammers direct to the forms. These hammers were doubtless inferior in effect to present equipment for external vibration.

In the present state of the art, vibration may be defined as a method of assisting concrete into place by increasing its mobility through rapidly applied impulses. Theoretically, these impulses should be repeated so rapidly that particles do not stabilize between them. There is a marked difference in the results obtained by jarring or jiggling

at rather low frequency compared with high frequency vibration. Observations indicate that the effectiveness of vibration increases with the frequency of the impulses but definite information is lacking on this relationship as well as on the proportionality of energy required and mass to be vibrated.

The mechanical principle involved in most vibratory appliances so far developed in this country is that of an unbalanced revolving weight.

Vibration as now practiced may be divided into five kinds as to method:

1. Vibration of forms.
2. Internal vibration.
3. Vibration of reinforcement, structural steel members, or track assemblies.
4. Platform vibration.
5. Unit vibration.

### Vibration of Forms

Vibration of forms is accomplished by attaching the vibrating element to the forms or by applying it to the forms through the medium of a spud to which the vibrator is attached. In this latter case, the result may be a combination of form and internal vibration if the rigid unit reaches the forms through the concrete.

Vibration of forms has a special field of use where the space inside the forms is inaccessible for other methods, such as the ships above referred to, tunnel and sewer linings, horizontal structural members, long columns and the like. It has been very successfully used in embedding or encasing structural steel shapes.

For structures of large mass the economic advantage of form vibration may depend upon the additional cost of the extra strength of forms required and its effectiveness will depend upon the depth to which the pulsations are transmitted.

### Internal Vibration

Internal vibration is accomplished by either attaching the vibrator to a member that is inserted into the fresh concrete, or by inserting the vibrator itself.

The use of internal vibrators is, of course, confined to form space that is accessible. When the vibrating element reaches the forms through the concrete, it combines form vibration with internal vibration. If the member is small and heavily reinforced the reinforcement may also be vibrated. Internal vibration is adapted to placement in both large and small masses.

### Vibration of Reinforcement

Vibration of reinforcement is accomplished by transmitting impulses by direct contact with the vibrating element or through the medium of a spud to which the vibrator is attached. In the case of structural shapes, the vibratory element may be attached positively to the structural members. A recent example of the latter is the embedment in cinder concrete of the structural shapes of the new Post Office building in Philadelphia. Vibration of assemblies of parts, as in embedment of car tracks, is accomplished by attaching the pulsating element to the rails.

Vibration of reinforcement may result from vibration of forms supporting the reinforcement, or from internal vibration. Embedment of structural steel shapes by direct vibration of them may be supplemented by internal vibration and/or vibration of forms.

### Platform Vibration

Platform vibration consists in applying the vibratory impulses to a plank or platform placed on the surface of the fresh concrete. It is especially adapted to vibrating

the surface of concrete in large form spaces, and has been very successfully used in the construction of concrete dams. Internal vibration may be combined with platform vibration.

### Unit Vibration

Unit vibration consists in the vibration of an entire unit and usually includes a Vibrating Table carrying the units in molds. It is especially adapted to the manufacture of concrete products, and has been successfully employed in making units weighing even more than one ton.

### Advantages

The advantages obtainable through the intelligent use of vibratory placement of concrete are:

1. Placement in forms where access for puddling or working by hand cannot be had, thus obviating the use of a mix of undesirable fluidity.
2. Economy in cement at a given water ratio, or a lower water ratio with a given amount of cement per unit of concrete.
3. Complete embedment of reinforcement—elimination of water and/or air filled voids under reinforcement or parts thereof.
4. Likelihood of economy in cost of placement.

### Disadvantages and Precautions

Some of the precautions to be observed with, and limitations resulting from vibratory placement, are:

1. Vibration of forms requires that the forms be stronger than necessary for hand placement.
2. The forms should be tight when vibrators are used on them. The action of vibrators promotes leakage.
3. While vibratory placement permits the use of drier mixes than hand placement, there is a limit beyond which honeycombing will result, but mixes unworkable by hand placement may become plastic with vibratory placement. The job conditions must govern.
4. Internal vibrators in the drier mixes should be withdrawn slowly.
5. There is a limit to mass thickness that can be effectively and economically pulsed by attaching the vibrators to the forms.
6. The amount of power necessary for proper vibration is a function of the mass to be vibrated. The energy applied must be sufficient to preserve mobility in the mass.
7. The laws governing strength and durability as affected by the water ratio and curing are not abrogated by vibratory placement. Lower cement factors may be used and increased density expected, but proper curing is just as essential as with any other placement method. Vibration must not be expected to cure segregation.
8. Experience does not show that any of the various methods of vibratory placement or combinations of them can be depended upon to eliminate air bubbles from the surface or mass of the concrete nor surface "sand streaking."
9. Long continued vibration will have no harmful effect where the consistencies and mixes best suited to vibratory placement are used. Under such conditions, *under* rather than *over*, vibration is to be feared and the length of time of

vibration may well be limited only by the progress of placement required by job conditions. With wetter consistencies and higher mortar content than necessary for vibratory placement, long time vibration may produce undesirable mortar segregation and should be avoided.

The suggested range in time of vibration is from 15 seconds for concrete of wet consistency to one minute for concrete of dry consistency, the actual time depending on the action of the concrete of the consistency used as affected by the type of vibrator applied.

10. The proper position of form vibrators with respect to the surface of the concrete must be judged by the observable effect on the concrete. The vibrator should not be so far below the surface as to greatly minimize its effect in producing mobility.

Rapid increase in the use of vibratory methods and in the development of vibratory apparatus is to be expected. Vibration in the placement of concrete, properly applied, will in many cases yield better results than hand placement.

#### SELECTED BIBLIOGRAPHY ON HIGH-FREQUENCY VIBRATION OF CONCRETE

Concrete Ships Constructed by U.S. Shipping Board, by Walter R. Harper. Proceedings, American Concrete Institute, 1922, Vol. 18, page 83.

The intricate mass of reinforcing steel made tamping or settling concrete around steel without leaving voids of great importance. Concrete was placed through panels from the inside. The forms were then vibrated using pneumatic hammers on the inside of outside form working through these openings also on the inside form. Inserted in hammer was steel bar with end upset. Concrete observed to move 15 ft. from point of application. Vibration proved very successful.

Large-Span Reinforced Concrete Bridges. Concrete and Constructional Engineering, June, 1931, Vol. 26, No. 6, page 385.

A study of views of M. Freyssinet, designer and builder of Elorn-Plougastel Bridge having reinforced concrete arch spans of 590 ft. By use of vibration or similar action to increase density of concrete and incidentally to reduce the high local internal stresses which would result from presence of minute cavities between the constituent parts of the concrete, it has become possible in manufacture of pre-cast concrete members, such as posts, poles, etc., to obtain crushing strength of 14,000 p.s.i. Pneumatic vibration was therefore used in placing concrete in these arches.

Concreting the Calderwood Tunnel, by W. R. Johnson. Proceedings, American Concrete Institute, 1931, Vol. 27, page 1189.

Tunnel 26 ft. wide with 11 ft. high sides and semi-circular crown of 13 ft. radius. Lining is 12 inches thick. Two electric vibrators attached to forms, one on either side and operated intermittently during placing.

Precise Concrete Control at Koon Dam. Engineering News-Record, December 31, 1931, Vol. 107, No. 27, page 1024.

Thomas W. Koon Dam, 12 miles north of Cumberland, Md., built with very harsh mix of concrete using electric vibrators mounted on heavy plank and operated by three men who stood on plank during operation. Maximum size aggregate 6½ in. Exceptionally smooth surface free from honeycomb was secured.

The Effect of Materials and Methods of Placing on the Strength and Other Properties of Concrete Bridge Floor Slabs, by L. W. Teller and G. W. Davis. Public Roads, December, 1931, Vol. 12, No. 10, page 237.

Cooperative investigation by Port of New York Authority and U.S. Bureau of Public Roads. Gravel, limestone and Haydite used for coarse aggregate, sand and Haydite for fine aggregate. Concrete placed by hand, by Vibrolithic process and by vibration with electric vibrator and air hammer. Latter two were of spud type. Concrete placed by vibrating methods had higher flexural and compressive strengths than hand placed concrete. Pull-out tests showed better bond resulted from vibrated methods, the improvement being greater for deformed bars than for plain bars. Absorption less

for vibrated specimens and unit weight higher. Surface hardness reduced by vibration probably due to water coming to surface bringing with it finer materials.

Formwork and Concreting Methods on Monolithic Sewer, by Harold L. Andrus. Concrete, March, 1932, Vol. 40, No. 3, page 12.

3435 ft. of 54 in. circular monolithic concrete sewer was built at Kalamazoo, Mich., in 1931. Forms were lined with wood fibre board to produce smooth surface. Sewer built in 112 ft. sections. Six electric vibrators were used, operated by gasoline-driven generator. Vibrators clamped at 8 ft. intervals to upper segment of circular form on inside. A very impervious concrete was obtained with 1:2:3 mix,  $5\frac{1}{2}$  gal. water per sack of cement, about  $2\frac{1}{2}$  in. slump and there were a minimum of water pockets and honeycomb spots. Expresses opinion that concrete could not have been placed around this form without vibrators.

The Segregation of Water in Concrete Placed in Deep Forms, by F. H. Jackson and W. F. Kellermann. Public Roads, June, 1932, Vol. 13, No. 4, page 64.

Tests made by Bureau of Public Roads by placing concrete in columns 8 by 48 in. ranging in height from 3 to 12 ft. Samples of concrete taken through port holes in sides of forms. Some of these analyzed and others used for making cylinders. Cores also taken. Electric vibrators were attached to forms by clamping them to  $2 \times 4$  inch battens. No serious segregation of concrete or water gain took place in concretes ranging in slump from 2 to 8 in. Factors that may have contributed to this were forms only 8 inches wide and relatively fine sand used. Placing by vibration produced about same average strength and uniformity as spading. A combination of spading and vibration appeared to increase strength beyond that obtained by either spading or vibration alone.

Stronger Concrete Pavement by Rapid Tamping, by C. E. Myers. Engineering News-Record, June 23, 1932, Vol. 108, No. 25, page 894.

Electric vibrator operated at about 3,500 r.p.m. was applied to strike-off board on track construction in Philadelphia. Concrete flowed down between ties, under bottom flanges of rails and against webs. Surface required no hand finishing. Cores showed dense concrete and high strength. Economy in labor also obtained on highway construction.

Compaction of Concrete Through the Use of Vibratory Tampers, by Raymond E. Davis and Harmer E. Davis. Journal, American Concrete Institute, June, 1933, Vol. 4, No. 9, page 365.

Vibrated Concrete, by T. C. Powers. Journal, American Concrete Institute, June, 1933, Vol. 4, No. 9, page 373.

Vibration imparts no new properties to concrete, the benefits result from ability to handle concrete of lower water content. Tests made in Portland Cement Association Laboratory show that, just as for hand-placed concrete, the quality of cement paste is chief factor determining strength, in both compression and flexure. Mortars have higher strength than concretes (at a given value of cement-voids ratio), especially in rich mixes when tested in flexure. Prolonged vibration increased strength of dry mixes slightly and reduced strength of wet mixes, maximum reduction being 10 per cent. These variables are of minor practical importance. Vibrated specimens have withstood 110 cycles of freezing and thawing without showing signs of trouble, indicating no impairment in resistance to weathering. Unlike hand-placed concrete, lower limit of sand factor in vibrated concrete is not indicated by strength tests but must be determined by behavior. Mixture must be plastic or become plastic under vibration. Water content may be reduced by 8 or 9 gal. per cu. yd. of concrete. Shrinkage tests not made but above reduction indicates shrinkage may be reduced nearly one-half that for comparable hand-placed concrete.

High Frequency Vibratory Machines for Concrete Placement, by M. I. McCarty. Journal, American Concrete Institute, September-October, 1933, Vol. 5, No. 1, page 49.

Discusses types of vibrators for different classes of work and mechanical requirements of electric vibrators. Frequencies between 4000 and 4500 r.p.m. efficient. Types of equipment used on different jobs including screed for placing grid decks.

Placement of Concrete by Mechanical Vibration, by A. W. Munsell. Journal, American Concrete Institute, September-October, 1933, Vol. 5, No. 1, page 54.

Discusses practical applications and time of application with relation to size of section. A few tests in laboratory of New York Port Authority indicated that mechanical vibration increased weight of concrete from 5 to 10 per cent. Expresses opinion that vibration should be made to pay for itself by minimizing patching and rubbing costs rather than by economizing on cement.

Fabricating 36-inch Reinforced Concrete-Steel Cylinder Water Mains, by J. F. Brett. Journal, American Concrete Institute, September-October, 1933, Vol. 5, No. 1, page 61.

Montreal Water Board installing 60,000 ft. of concrete pipe consisting of outside shell  $2\frac{1}{4}$  in. thick placed by vibration and inside shell  $1\frac{1}{4}$  in. thick placed by centrifugation. Pipes are  $16\frac{1}{2}$  ft. long and weigh 5 tons each. Specifications call for compressive strength of 4500 p.s.i. at 28 days. Pipes cast vertically in steel molds with 4 vibrators attached which are kept going continuously while concrete is being placed which is also continuously. Mix 1:1.6:1.9 with 35 lb. water per cu. ft. of cement gives strengths from 5,600 to 6,500 p.s.i. at 28 days. Vibrators now used on all work. Slump should be less than 2 in. on bridge and similar construction. An excess of paste tends to hold air bubbles.

Vibration in Making Roof Deck Slabs, by A. B. Shenk. Journal, American Concrete Institute, September-October, 1933, Vol. 5, No. 1, page 63.

Precast concrete slabs for roof decks are made in steel molds. Two pneumatic vibrators are attached to under side of mold producing a satisfactory finish with a lower water-cement ratio. Seemingly the greater the amplitude the more rapidly the concrete flows into position. Greater speed seems to produce slower movement but with a corresponding increase in density. Proper balance for this work found to be about 2000 vibrations per min.

## SECTION 2

### CENTRAL MIXED AND TRANSIT MIXED CONCRETE

Within the last few years large investments have been made in central plants for the assembly of materials and the batching, mixing and distribution of concrete to construction jobs over wide areas. At first there was well grounded objection to the output of such plants due to the compacting and segregation of concrete transported for considerable distance in ordinary truck bodies. This objection was met by the development, first of "agitator" trucks and later, truck mixers furnished with devices to control the introduction of water, the time of mixing, etc.

These central plants introduce various complications in the tasks of Engineers, Inspectors and Contractors concerned with their product. Some of the advantages and disadvantages of this Industry may be listed as follows:

#### Central Mixed Concrete—Advantages

The chief advantage of a central mixing plant on the manufacturing side is that a permanent location and comparatively large output justify the installation of adequate facilities for the proper storage and classification of aggregates, for accurate batching by weight, and for regulation of temperature and control of water-cement ratio. Good water supply is also available.

Most up-to-date plants employ agitator trucks to transport the mixed concrete from the central mixing plant to the job.

These agitator trucks should insure the transportation of concrete over long distance without segregation of the materials and promote easy discharge of concrete in good condition for use on the job.

The advantages to the purchaser include:

(a) Saving of storage and care of materials. This is a real advantage on many small railroad jobs where space is limited, and often eliminates the necessity for a construction track at the job, thus contributing to economy.

(b) The concrete plant including mixer and appurtenances are dispensed with.

(c) Labor costs are reduced as it is no longer necessary to keep a concrete gang "standing by" waiting for concreting operations.

### Disadvantages

(a) Difficulty of proper inspection. On the smaller railroad jobs, it is expensive to furnish an inspector at the central plant in addition to the man at the job, the result being that otherwise entire reliance must be placed in the operator at the central plant to proportion and manufacture the concrete according to instructions. Also, if poor concrete arrives on the job, it is impossible to correct conditions promptly as there may be several truck loads in transit.

(b) Possibility of breakdown of truck or delay due to traffic, etc.

(c) Difficulty in connection with special placing equipment such as elevating requirement.

(d) If the purchaser furnishes his own bin tested cement, various difficulties are encountered to insure check of shipments, and segregation of the owner's cement for use in his work.

(e) Depending on the distance of the job from the central plant, delays and irregularities in delivery may increase costs or cause disorganization on the work.

### Transit Mixed Concrete

Prior to the introduction of transit mixers, concrete mixers were fairly well standardized and the relationship of capacity to diameter of drum and peripheral speed had been established within certain limits. The introduction of mixer trucks of various designs raises a question as to their relative merits.

In general, it is recommended that the transit mixers should be of cylindrical form with the barrel of a diameter large in proportion to its length, and with the mixing mechanism driven by an engine independent of the truck motor. Some manufacturers do not recommend truck mixers of over  $3\frac{1}{2}$  cy. capacity.

The considerations listed as to the advantages and disadvantages of central mixed concrete apply to a considerable extent to transit mixed concrete and in addition, the following should be noted:

### Advantages

The batched materials may be held in the truck mixer until a predetermined point enroute and water added and mixing started then, or the mixing process may be deferred until the truck is at the job and mixing can be done under the supervision of the inspector. In this case, only the batching is done off the job.

In general, the equipment of mixer trucks employed by responsible distributors consists of relatively costly units which are well serviced and maintained by garage mechanics, and are therefore, apt to be in better physical and mechanical condition than the ordinary run of mixers in use. It is entirely feasible to inspect these trucks and their operation before approving their use on any particular job, and instructions should be issued accordingly.

### Disadvantages

It has happened in individual cases, that obsolete or substitute trucks have been put in service or the order switched to another outfit not properly equipped for the service specified. A serious difficulty in the purchase of concrete mixed in transit is the disposition of batches which should be rejected after delivery. It is probably impossible to eliminate occasional mistakes in batching, which may be due to confusion in orders, or in the amount of water or other defects resulting in batches which should be wasted if delivered by a mixer truck. These difficulties can be anticipated or corrected by an inspector when the entire operation of manufacture is under observation and control on the ground.

## Specifications

Reference is made to proposed Tentative Specifications for Ready Mixed Concrete—A.S.T.M. C-33 T. In this specification, under Composition of Concrete, a broad approach to the subject is made when the following methods of proportioning are described:

- (8) By volume
- (9) By weight
- (10) In terms of quantity of cement
- (11) Based on water-cement ratio
- (12) Based on strength

Under the heading of mixing are two sections which apparently place the entire responsibility for the results of the mixing operations on the manufacturers of the equipment leaving to the customers, Engineers or Inspector very little discretion under the specifications, viz:

(19) CENTRAL MIXED PLANT.—In the case of the stationary mixers the mixer drum shall be of adequate size to accommodate the maximum batch, and shall be in accordance with the Concrete Mixer Standards adopted by the Mixer Manufacturers' Bureau of the Associated General Contractors of America. The mixer shall be rotated at the rate recommended by its manufacturer.

(20) TRUCK MIXING.—In the case of truck mixers, the size of batch shall not exceed the rated capacity of the mixer as stated by the manufacturer and as stamped in metal at a prominent place on the mixer. The mixer shall be water-tight when closed. Each batch of concrete shall be mixed not less than 50 nor more than 150 revolutions of the mixer at the rate of rotation specified by the manufacturer as mixing speed. Any additional mixing shall be done at a slower speed specified by the manufacturer for agitation.

Doubtless the manufacturers' opinions as to the capacity, speed, and conditions of operating their equipment are based on tests and experience with average conditions, but variations in the comparative weights of aggregates, conditions as modified by low temperatures or long hauls, and the methods of deposit in the forms may modify the mixing requirements considerably and should be given consideration in any general specification for Ready Mixed Concrete.

## SECTION 3

### SEGREGATION

There are three kinds of segregation:

(1) Segregation in parts of structures of materials in a finely divided state or of low specific gravity. This type of segregation is induced by the flowing action of wet concrete within the forms and the washing action in extremely wet mixes. The materials thus separated out are segregated in horizontal laitance seams or are incorporated in considerable quantity in the concrete in parts of the structures. Such concrete and laitance seams have low resistance to weathering and particularly to freezing. Excepting when concrete is deposited in water, this type of segregation is always associated with wet mixes, and its prevention lies in maintaining a safe-working consistency. When concrete is deposited in water, the buckets or tremies must be so designed and so manipulated as to minimize the flow and wash.

(2) Segregation of water and its incorporation in concrete in parts of structures in quantity in excess of that designed for the mix, results from the tendency of water to move upward through the concrete while in a plastic state. This movement, result-

ing in what is termed water gain, may, unless corrected or controlled, result in a water-cement ratio too high for durability under severe exposure. This type of segregation is difficult to control or minimize.

The most essential basic requirement for the control of water gain is the securing of a high degree of workability and the maintaining of a suitable consistency. In this connection, refer to the report of this committee, published in the 1932 Proceedings, and in Bulletin 344, where mention is made of the need, at times, for correction or control of water gain by placing concrete of dry consistency to absorb some of the rising water, and of adequate provision in specifications to provide for this.

(3) Separation of mortar from coarse aggregates in concrete of safe-working consistency may be due to faulty type or condition of the mixer, the discharge from the mixer, the conveying, whether by barrow, belt, buggy, bucket, chute or truck, the discharge into the forms, or to the manipulation within the forms. This type of segregation makes more difficult the puddling or compacting of concrete without honeycombing or stone pockets, especially in reinforced concrete where it is necessary to protect reinforcement from corrosion.

This type of segregation can be detected by visual inspection of the concrete as it is being levelled to place in the forms. Investigation of the manipulation of the concrete in its mixing, conveying, depositing and compacting should reveal the cause or causes and suggest the remedy insofar as manipulation of the mixed concrete is involved. It should be borne in mind, however, that a basic requirement, in obviating this type of segregation is the maintaining of a high degree of workability at the driest consistency appropriate for the type of structure and method of compacting.

### Workability and Consistency

The right way to obtain workability of the concrete suitable to the method of compacting, is through the proper design of the mix, with respect to the size, quantity and grading of the aggregates. Of special concern is the relative proportions of sand and coarse aggregates and the grading of the sand. The first can be determined by trial batching. Probably the most significant factor in graded sand is the percentage passing the No. 48 (or No. 50) sieve. 15 per cent is preferable, although 10 per cent is the minimum allowable.

Failing this requirement, the sand may well be rejected or sufficient fines either in the form of fine sand, added cement, or an admixture, subject to the approval of the Engineer, may be added to compensate for deficiencies in fines.

It should be borne in mind that a high degree of workability in concrete gives it those characteristics which permit of easier placement at a less liquid consistency and, for compacting by puddling, a stiff, sticky consistency, which tends to hold the aggregates together in the mass, can usually be maintained. The factors contributing to better workability tend also to stabilize the water in the concrete when in a plastic state, thus tending to minimize water gain. For example, when pronounced sand streaking occurs along the forms, the remedy usually lies in increasing the fines in the sand and the use of a less liquid consistency. When the sand streaking occurs to a pronounced degree, then water gain will be pronounced until corrected or controlled.

A high degree of workability and the maintenance of a stiff consistency will tend to stabilize water in the concrete, minimize water gain and therefore sand streaking as well as entrapment of water under the coarse aggregate.

## Appendix C

### (5) FOUNDATIONS

D. B. Rush, Chairman, Sub-Committee; M. F. Clements, W. F. Cummings, G. F. Eberly, G. R. Smiley, A. W. Smith, I. F. Stern, G. E. Tebbetts, Jamison Vawter, C. C. Williams, J. J. Yates.

#### GENERAL SPECIFICATIONS FOR FOUNDATIONS OF RAILWAY STRUCTURES

##### 1. Definitions

**FOUNDATION.**—The natural material which supports the structure, and its loads, whether strengthened or not by the use of piles or other means to secure adequate bearing.

**"SUBSTRUCTURE"** refers to that part of the structure which supports the superstructure and its loads.

These definitions are presented for adoption for printing in the Manual.

##### 2. Drawings

After the contract has been awarded and before any work is commenced, the Contractor shall submit to the Engineer for approval duplicate prints of drawings which supplement the detail plans of the Company, showing the proposed methods of doing the work and details of construction work proposed. The tracings of these drawings or other reproducing prints shall be the property of, and be delivered to the Company after the completion of the contract. These drawings shall be twenty-four (24) by thirty-six (36) inches in size, including margins. The margin at the left end shall be one and one-half ( $1\frac{1}{2}$ ) inches wide and the others one-half ( $\frac{1}{2}$ ) inch. The title shall be in the lower right-hand corner. No changes shall be made on any approved drawing without the consent, in writing, of the Engineer. The Contractor shall be responsible for the correctness of his drawings, although the drawings may have been approved by the Engineer.

##### 3. Excavation

All excavation shall be made to permit the placing of the substructure. The Contractor shall maintain the excavation in a safe condition during the construction period.

##### 4. Open Construction—With Sheet piling

Where it is necessary to retain the earth, the sides of the excavation shall be held by sheet piling. Sheet piling if tight may be used as a form for concrete to the top of the lowest footing course and may be left in place at the option of the Contractor, but if so left, it shall be cut off at the ground without extra cost to the Company.

##### 5. Cofferdams, Crib, Open Caissons, etc.

Where it is necessary to make excavation in water, a suitable cofferdam, crib, open caisson or similar type of construction shall be used to exclude the water, in order to permit the excavation of the material above the foundation, so that the substructure may be placed directly upon it. The Contractor may select his own type of construction, subject to the approval of the Engineer.

## 6. Excavation Materials Classified

### (a) CLASSIFICATION OF MATERIALS

(A) Rock shall include all rock occurring in masses of one cubic yard or more in volume or in strata exceeding six inches in thickness which require blasting for economical removal.

(B) Common shall include all material other than rock.

(C) Slope Excavation shall include all material excavated without the use of sheeting and bracing, and which has natural earth slopes at the sides of the excavation.

(D) Pit Excavation shall include all material excavated in a pit having the sides retained by sheeting and bracing. Where slope excavation and pit excavation are required for the same foundation, the dividing plane between them shall be the average ground elevation at the sides of the pit.

(E) Dry Excavation shall include all material removed during the excavation period, from above that elevation at which the pit can be kept sufficiently clear of water by ditching or by the continuous service of one man using a four-inch hand-operated diaphragm pump to permit the excavation to be done.

(F) Wet Excavation shall include all material removed during the excavation period, from below that elevation at which the pit can be kept sufficiently clear of water by ditching or by the continuous service of one man using a four-inch hand-operated diaphragm pump to permit the excavation to be done.

### (b) CLASSIFICATION OF WORK

#### (1) DRY EXCAVATION

(a) Dry rock excavation.

(b) Dry common slope excavation.

(c) Dry common pit excavation.

#### (2) WET EXCAVATION

(a) Wet rock excavation.

(b) Wet common excavation.

## 7. Disposal of Surplus Material and Backfill

If the Engineer considers the surplus excavated material suitable, it shall be used for backfilling foundation pits to the original ground line and surplus material not so used will be disposed of as the Engineer may direct.

## 8. Preparing Natural Earth Foundation

The material upon which the substructure is to be placed shall be excavated to the outline of the footing course, as shown on the plans, or as established by the Engineer, and shall be of sufficient size to permit the placing of the full width and length of the footing shown with full bed. Excavation which causes rounded or undercut corners and edges of footings will not be permitted. The elevations of the bottoms of footings, as shown on the plans, shall be considered as approximate only and the Engineer may order, in writing, such changes in dimensions or elevations of footings as may be necessary to secure a satisfactory foundation. When the foundation bed is solid rock, all loose or disintegrated portions of the rock shall be removed. Sloping surfaces shall be cut to a level, or to stepped level planes. All open fissures in rock foundation beds shall be filled with concrete before the substructure is started.

## 9. Removal of Water from the Excavation Pit

In the open cofferdam method, the cofferdam shall be made of such materials as to provide a pit, the sides of which are practically impervious to water. Suitable hand or power-driven pumps shall be provided to remove the water, so that workmen may enter the pit and remove the excavation material in a practical and economical manner. If the materials underlying the foundation are porous to the extent that it is impracticable

to remove the water by pumping, the Engineer may direct that the excavation material be later removed by dredging and the foundation be prepared without removing the water. Under these conditions, after the excavation has been completed to the satisfaction of the Engineer, a concrete seal shall be placed by depositing concrete through water, in accordance with A.R.E.A. Manual, page 573. The seal may be considered a portion of the foundation or of the substructure, as stated in the agreement. The thickness of the seal shall be sufficient to overcome hydrastatic pressure on the structure of which it becomes a part.

Where a depth of water is encountered in the cofferdam that will result in the creation of a head under the footing course, provision shall be made in the construction of the cofferdam to provide sufficient space between the inside of the cofferdam and the substructure forms to permit of drain to a sump.

Pumping shall be from a sump separated from green concrete to avoid wash of concrete materials. Pumping to unwater sealed cofferdam shall not be commenced until the concrete has had a set sufficient to overcome hydrostatic pressure.

#### 10. Strengthening the Foundation Material with Piles

In general, the detail plans will show the foundation piles required. If they are not provided for and the Engineer, after an examination of the foundation, considers the earth has insufficient bearing value to support the structure, he shall direct that it be strengthened by the use of foundation piles or by other means. The excavation shall be cleaned of any loose or displaced material and débris before and after the foundation piles are driven and before the substructure is placed.

The Contractor shall submit full details as to the method and equipment he proposes to use in the driving and cutting off of the piles and shall secure the approval of the Engineer before any work is started.

#### 11. Foundation Piles

Foundation piles shall be timber, concrete, steel, or a combination as shown on the plans approved by the Engineer.

(a) Timber piles may be treated or untreated. They shall be in accordance with the A.R.E.A. Specifications for First or Second-Class Piles as required. If treated piles are used the treatment shall be in accordance with the A.R.E.A. Specifications for the Preservative Treatment of Wood. They shall be treated unless submerged at all times.

(b) Concrete piles may be "Cast-in-Place" or "Precast". The Contractor shall submit plans and specifications for the type of pile he proposes to furnish and must secure the written approval of the Engineer before work is commenced.

(c) Steel piles shall be manufactured from copper-bearing structural grade of steel, as shown on the plans, approved by the Engineer.

(d) Combination piles shall be manufactured according to plans approved by the Engineer.

#### 12. Pile Driving

Pile driving shall be in accordance with the A.R.E.A. "Pile Driving Principles of Practice" and also in accordance with the following:

The Engineer shall instruct the Contractor in the work to be done and will approve and direct that the piles shall be driven to true location and proper elevation, within the tolerances specified on the plans. Piles injured in driving, or driven out of place, shall be replaced by other piles. A pile driven too low to be cut off at the proper elevation shall be replaced. A pile damaged in driving and unfit for the place in which it is driven shall be replaced or repaired. A pile forced up due to the driving of surrounding piles shall be redriven. Piles shall be cut off level to proper elevation.

### 13. Measurement and Basis of Payment

The unit of measurement will be according to legal standards of weights and measurements.

The work to be paid for shall be determined by the Engineer from the original plan dimensions, or as altered by him, applying the unit rates to the quantities so determined. The Contractor will be paid on the basis of the original summation of his proposal, adjusted for the additions and reductions in quantities based on his unit prices for such changes in quantities.

Measurement for payment shall be as follows:

(a) Foundation excavation (unit = cubic yard). The price per cubic yard shall include the removal of all material encountered above the foundation and the backfilling of foundation pits around completed masonry, using surplus excavated material, as follows:

- (A) The volume of Dry Excavation, slope methods, shall be obtained from the actual measurement of all material removed in slope excavation, exclusive of any material measured by the pit method.
- (B) The volume of Dry Pit Excavation shall be the volume of a prism bounded by vertical planes at one foot outside of the footing course, exclusive of any material measured in slope excavation and exclusive of any material included in the wet excavation prism.
- (C) The volume of Wet Excavation shall be the volume of a prism bounded by vertical planes at one foot outside of the footing course and between the horizontal planes at the water level defined in paragraph No. 6, Section F, and the average elevation of the excavated foundation.

(b) Backfill, new material (unit = cubic yard in place). The price per cubic yard for new material other than that from excavation placed in backfill shall cover the cost of supplying in place the required new material for such backfill.

(c) Piles delivered (unit = linear foot). The prices per linear foot for untreated timber and treated timber, premoulded precast concrete, steel and combination piles, shall include the supply, delivery and unloading at the site, of piles in number and lengths as approved by the Engineer.

(d) Pile driving (unit = linear foot). The price per linear foot shall include all work of any kind in connection with the driving, including the cutting off. The price will be applied to the net linear feet of piles left in the finished structure.

(e) Pile Shoes (unit = each). The price each covers the pile shoes actually placed.

(f) Cast-in-Place Concrete Piles (unit = linear foot). The price per linear foot shall cover in full the total cost of piles cast-in-place. The price will be applied to the total length of piles in place in the finished structure.

## Appendix D

### (6) TENTATIVE SPECIFICATIONS FOR LINING RAILWAY TUNNELS WITH CONCRETE

G. F. Eberly, Chairman, Sub-Committee; G. E. Boyd, Kennerley Bryan, Jr., M. F. Clements, Maurice Coburn, W. F. Cummings, O. V. Parsons, I. L. Pyle, G. R. Smiley, H. H. Temple, C. A. Whipple, D. E. Woosley.

#### GENERAL

##### Scope

1. These specifications cover the lining of new tunnels and the relining of old tunnels through ordinary formations which involve no special features.

## (II) DESIGN

### Interior Dimensions

2. The interior dimensions shall not be less than those shown as standard for single and double track tunnels in the American Railway Engineering Association's Specifications for Roadway (Fig. 1).

### Footings

3. Where footings are required they shall be at least 2 ft. 0 in. in depth and as much more as necessary to secure a good foundation. The footings shall be at least 2 ft. 0 in. in width and the top shall be at the elevation of sub-grade. The face of the footings shall be in the same vertical plane as the face of the sidewalls (Fig. 1). Each section of footing shall be substantially keyed to each adjacent section.

### Floor and Ballast Walls

4. If considered desirable, a concrete floor and ballast walls shall be installed. The floor shall be at least 6 in. thick and shall slope  $\frac{1}{2}$ -inch in 12 in. from the center line of the tunnel at the elevation of the sub-grade towards the sidewalls. The ballast wall, with the toe of the wall at least 12 in. from the face of the sidewall and the top not more than 3 in. below the top of the tie, shall be 12 in. wide at the top and 24 in. at the bottom (Fig. 1).

### Sidewalls

5 (a). The sidewalls shall be at least 2 ft. 0 in. thick, when no temporary supporting of the face of the excavation is required. The space between the face of the sidewall form and the face of the excavation shall be entirely filled with concrete, except that durable rock may be substituted for concrete to fill large holes back of the normal line of excavation. If rock is used it shall be rammed into place (Fig. 1).

(b) If temporary supporting of the face of the excavation is required, the space between the lagging and the face of the excavation shall be firmly packed with durable rock, rammed into place. The space between the face of the sidewall form and the lagging shall be entirely filled with concrete with a minimum thickness of 18 in. in front of the temporary supports (Fig. 1).

Each section of sidewall shall be substantially keyed to each adjacent section.

### Arch

6 (a). The arch shall be at least 2 ft. 0 in. thick when no temporary supporting of the face of the excavation is required. The space between the face of the arch forms and the face of the excavation shall be entirely filled with concrete (Fig. 1).

(b) If temporary supporting of the face of the excavation is required, the space between the lagging and the face of the excavation shall be firmly packed with durable stone, rammed into place. The space between the face of the arch form and the lagging shall be entirely filled with concrete with a minimum thickness of 18 in. in front of the temporary supports (Fig. 1).

### Refuge Niches

7. The refuge niches shall be 18 in. deep, 4 ft. 0 in. wide and 7 ft. 0 in. high. They should be spaced 100 ft. apart on each sidewall, and staggered so that the niches on opposite walls shall be 50 ft. apart. The bottom of the niches shall be at the elevation of the bottom of the track tie.

## Drainage Openings

8. Vertical and diagonal openings or tile drains shall be installed in the rear of the concrete lining with outlets through the sidewalls to provide ample drainage where water is encountered. The outer end of outlets shall be 6 in. above the bottom of the gutter. Sub-drains shall be provided under the concrete floor where water is encountered. Sufficient tile shall be installed in the ballast walls to provide drainage for section of floor between ballast walls.

## (III) CONCRETE

### Specifications

9. The specifications for Portland Cement Concrete, Plain and Reinforced, of the American Railway Engineering Association, shall be used in the manufacture and placing of the concrete, together with the additional provisions given herewith.

### Proportioning

10. The concrete shall contain not to exceed 5.5 gallons of water per sack of cement and have a minimum compressive strength of 3,000 lb. per square inch, in 28 days.

## (IV) FORMS

### Length

11. The length of forms for continuous placement of concrete between construction joints shall be limited by the ability of the placement method to get a complete and homogenous filling of the space behind the forms, but in no instance shall the length be more than 40 ft.

### Removal of Forms

12. The forms shall not be removed in less than 48 hours where the surrounding temperature is 70 deg. or over. When the temperature is below 70 deg., the time shall be lengthened as directed by the engineer.

## (V) PLACING CONCRETE

### Hand Placing

13. Concrete placed by hand shall be of such consistency that it can be thoroughly packed so as to entirely fill the forms. This consistency shall be obtained without varying the water-cement ratio.

### Pneumatic Placing

14. Pneumatic placing of concrete shall be done with a concrete placing machine which blows the concrete through a pipe line with compressed air. The air pressure and the consistency of the concrete shall be so regulated, without varying the water-cement ratio, that the coarse aggregate shall not be blown away from the mortar matrix when the concrete issues from the end of the delivery pipe. Flexible pipe branches shall be provided, when necessary to deliver the concrete at approximately its final position in the lining. The concrete shall be shot into a metal baffle box surrounding the end of the delivery pipe, or the end of the delivery pipe shall be kept as close to the mass of concrete as conditions will permit, and at no time more than 5 ft. away, so as to prevent separation of the mass and permit continuous inspection.

### **Pumping**

15. Placement by pumping shall be done with a plunger pump which forces the concrete through a pipe line by direct pumping action without using compressed air in the line. Concrete shall be pumped as nearly as possible to its final place of deposit, using flexible pipe branches where necessary.

### **Shotcrete**

16. Placement of Shotcrete shall be done by building up a lining by shooting on the Shotcrete in thin layers with a pneumatic hopper machine in which the properly proportioned dry cement and sand are pneumatically mixed and forced through a hose to a nozzle attached to the end of the hose, where water under pressure shall be introduced into the dry mix just prior to being sprayed into place.

### **Order of Placing**

17. If a floor is not installed, a section of footings, sidewalls and arch shall preferably be placed in one continuous operation.

When a floor is installed, the floor, ballast walls, footings and the lower 2 ft. of sidewalls should preferably be placed monolithically.

### **Compacting**

18. Concrete, during and immediately after depositing, shall be thoroughly compacted, preferably by means of vibrators, which can be applied to or in the mass of concrete.

### **Laitance Seams and Bonding Surfaces**

19. The consistency of the concrete and method of placement shall be such that no laitance seams are formed at fill planes. If so formed, they shall be completely removed and the forms and the progression of the work shall be such that this may be done. Concrete surfaces on which new concrete is to be deposited shall be thoroughly cleaned of all laitance, dirt and water before concrete is placed.

### **Drainage During Placing**

20. Separate and distinct provision for drainage shall be made where necessary to prevent the placement of concrete in water or contact of the fresh concrete with moving water. Effective weeps and drains shall be provided where necessary to prevent hydraulic pressure against the lining until, in the opinion of the engineer, sufficient strength has been acquired to withstand the pressure.

### **Curing**

21. After the forms are removed the surface of the tunnel lining shall be kept wet for a period of at least seven days.

## **(VI) CONSTRUCTION AND EXPANSION JOINTS**

### **Construction Joints**

22. No construction joints or fill planes shall be formed in such locations as to reduce the effectiveness of the lining in resisting pressure from the surrounding earth or rock.

### **Expansion Joints**

23. No expansion joints shall be provided other than the construction joints. When necessary, non-corrosive water stops shall be installed at construction joints.

FIG. 1.  
Concrete Lining.  
Single Track-Tangent.

## Appendix E

### (7) PNEUMATICALLY PROJECTED CONCRETE

T. L. Condron, Chairman, Sub-Committee; G. E. Boyd, Kennerly Bryan, Jr., W. K. Hatt, A. C. Irwin, D. A. Ruhl, G. E. Tebbetts, H. H. Temple, L. W. Walter.

#### TENTATIVE SPECIFICATION FOR SHOTCRETE

##### NOTE A.

Shotcrete is here used as a brief descriptive term (not copyrighted) for a material consisting of Portland cement, sand and water placed pneumatically by means of a machine that discharges water and pre-mixed cement and sand, under regulated pressures, through pipes or hose, and a discharge nozzle, the water being combined with the cement and sand at the nozzle.

##### NOTE B.

Shotcrete machine is here used as a brief description term (not copyrighted) for a pneumatic machine used to place Shotcrete.

##### NOTE C.

All of the constituent materials of Shotcrete shall conform to the latest Standard Specifications for Portland Cement Concrete of the American Railway Engineering Association.

#### GENERAL

1. All Shotcrete work shall be done under the supervision of experienced foremen, using only experienced men as machine and nozzle operators.

2. Shotcrete shall consist of a mixture of Portland cement and sand, in the proportion of one bag of cement to three cubic feet of sand, placed by pneumatic pressure through a Shotcrete machine, with the proper amount of water for hydration applied in the mixing nozzle. The cement and sand shall be pre-mixed dry in a batch mixer and screened through a  $\frac{1}{4}$ -inch screen before being placed in the hopper of the Shotcrete machine. By the term "dry" is not meant that all moisture must be removed from the sand but that it shall have only the normal water content of bank sand, that is from 3 per cent to 8 per cent.

3. Water used in hydrating the material at the nozzle shall be clean and free from all substances that would interfere with the setting qualities or strength of the cement. Water pressure in the delivery pipe shall be maintained at 10 to 20 lb. per sq. in. above the air pressure in the Shotcrete machine.

4. The volume of air passing through the lower chamber of the Shotcrete machine, as measured by a suitable air meter, shall be that which will produce a nozzle velocity of from 375 to 500 feet per second when a  $\frac{3}{4}$ -inch diameter nozzle tip is used; 425 to 525 feet per second when a 1-inch diameter tip is used; and 475 to 550 feet per second when a  $1\frac{1}{4}$ -inch diameter tip is used. In case an air meter is not available, a uniform pressure of not less than 35 lb. per sq. in. shall be maintained in the placing machine. Where the length of the hose between the placing machine and the point of placement exceeds 100 feet horizontally and/or 25 feet vertically the pressure shall be increased so as to secure satisfactory velocity at the nozzle.

5. Shooting strips shall be employed to insure square corners, straight lines and proper thickness of Shotcrete. These shooting strips shall be so placed that they will not trap rebound.

6. When "shooting" any surface, the stream of flowing material from the nozzle shall impinge as nearly as possible at right angles to the surface being covered. All deposit of loose sand shall be removed prior to shotcreting. Should any such deposit be covered with Shotcrete, it shall be cut out and removed by the contractor without additional compensation.

7. After the main body of Shotcrete has been shot into place, high spots are to be removed with a sharp-edged screed or trowel in such a way as not to drag the Shotcrete surface. After this has been done and the shooting strips have been removed, the entire surface is to be given a flash coat of Shotcrete which is not to be troweled or screeded but may be brushed with a wet brush if a brush finish is desired.

8. The Shotcrete shall be kept wetted for at least four days after placing. No Shotcrete shall be placed when the temperature of the surrounding air is below 40 degrees Fahr., or against surfaces in which there remains any frost.

9. Measurement for all Shotcrete areas shall be the exposed surface area of the Shotcrete.

#### ADDITIONAL REQUIREMENTS FOR SHOTCRETE PROTECTION OF STRUCTURAL STEEL

10. Steel members to be protected with Shotcrete shall be cleaned thoroughly of all loose rust, scale, grease, dirt, paint or any other foreign material that will prevent proper adhesion between the Shotcrete and the steel. New steel members that are to be protected with Shotcrete should not be painted or oiled.

11. The Shotcrete encasement of steel members shall follow generally the outline of the members. It shall have a thickness of  $1\frac{1}{2}$ -in. except at the underside and edges of lower flanges of floorbeams and girders where the thickness shall be 2 inches, placed in not less than two operations, with an interval of two to three hours between operations. The thickness specified is to be measured from the surface of the steel member and not from the tops of rivet heads.

12. Shotcrete used for the encasement of steel shall be reinforced with one layer of 2 in.  $\times$  2 in. — 12ga  $\times$  12ga or 3 in.  $\times$  3 in. — 10ga  $\times$  10ga galvanized electric welded wire fabric weighing not less than 37 lb. per 100 sq. ft. This reinforcing shall be cut in sheets and properly bent so that it may be spaced approximately  $\frac{1}{2}$ -inch away from the surface of the steel members, and so that it will have a minimum coverage of  $\frac{3}{4}$ -inch of Shotcrete. Adjacent sheets of mesh shall be lapped one and a half meshes and securely wired together. On all built-up steel girders, I-sections and channels, holes shall be shop-punched through the webs of the members for tying the reinforcing mesh in place. On girders and I-s of more than 20 inches depth, two lines of holes shall be punched, or drilled, one line just below the top flange and one line just above the lower flange. These holes shall be not more than three feet apart in each line. Where the webs are over five feet in depth, an additional line or lines of holes shall be punched or drilled so that the horizontal lines shall not be more than 3 ft. 6 in. apart. Three-eighth-inch ( $\frac{3}{8}$ -inch) round rods shall be so held in place by wire ties through the holes in the webs, that the rods shall be at least  $\frac{1}{4}$ -inch clear of the webs, and the reinforcing mesh then securely wired outside of these bars with wire ties approximately 18 inches apart. Care shall be taken to prevent the mesh being drawn against the flanges of the steel members.

13. Instead of punched holes in webs, specified in paragraph 12 above, for use in attaching  $\frac{3}{8}$ -inch round rods, suitable connecting pieces may be welded to the webs and the  $\frac{3}{8}$ -inch round rods in turn welded to the connecting pieces if approved by the Engineer.

14. "Gunit", "Guncrete," or other similar materials commonly known by copyrighted names, if complying with these specifications, will be acceptable where Shotcrete is specified.

### Action Recommended

This report is submitted as information with the recommendation that the subject be continued.

## Appendix F

### (8) DESIGN OF EXPANSION JOINTS INVOLVING MASONRY STRUCTURES

C. A. Whipple, Chairman, Sub-Committee; G. E. Boyd, M. Coburn, L. V. Haegert, J. A. Lahmer, W. M. Ray, G. E. Robinson, D. E. Woosley, W. K. Wyatt.

During the last two years the Committee collected from a number of carriers plans covering various types of joints involving masonry structures to meet various conditions, and last year submitted sketches appearing under Appendix E, Bulletin 353, page 599, as information.

This year the Committee has made further study of the joints submitted, with criticisms and suggestions of the various details, and offers the following basic principles to be observed in determining the details of expansion joints:

Primarily, expansion joints should permit volume change movements, without developing injuriously high local stresses.

Such movements include the shortening as well as lengthening of adjacent members, and repeated reversals of such movements.

Drainage, waterproofing, and traffic considerations complicate the design, but must not be allowed to cause violation of the purpose of such joints.

The simplest design effectively to meet conditions should be chosen. The possibility of changing service must be considered.

Expansion Joints may be classified as follows\*:

#### (1) Open Joints

- (a) Unrestrained motion—free drainage.
- (b) Unrestrained motion—drainage provided.

#### (2) Filled Joints

- (a) No waterproofing.
- (b) Waterproofing required.

#### (3) Keyed Joints

- (a) To hold alinement.
- (b) To transfer stress.

#### (4) Concealed Joints

### GENERAL

Details that result in entrapment of water or dirt are highly objectionable. Joints should be self-draining and self-cleaning if practicable.

Details that permit minor members to contact before the heavier members do, cause unsightly and annoying defects.

\* These classifications apply to both horizontal and vertical expansion joints.

Joints should be provided to prevent weaker members, such as railings, from acting monolithically with major parts.

Materials highly resistant to deterioration should be used.

Joint fillers should be elastic rather than plastic. Their physical texture should provide volume relief locally with a minimum of extrusion.

Sliding joints, those that are shrouded or concealed particularly, should be designed to provide full movement without developing injurious local stresses. Care should be exercised to insure that sliding surfaces shall be parallel and parallel to the direction of movement.

Provision should be made for the free drainage of water to prevent entry into the joint.

When water cannot be prevented from passing through expansion joint it should be collected and disposed of in such manner as to prevent falling on the structure.

### COMMENTS ON JOINTS SUBMITTED

FIG. 1.—This joint has given six years' satisfactory service supporting highway traffic, providing expansion for both steel and concrete, but it is recommended detail be revised and the following changes made:

1. Floor beam to be raised to provide cheaper steel fabrication.
2. Provide anchorage for horizontal leg of the top angle. Provide anchorage top angle both sides of joint for horizontal leg. There should be straps extending diagonally downward.
3. Traffic plate should be attached by tap screw for renewal purposes.

FIG. 2.—Represents a joint supporting ordinary highway traffic and has given satisfactory service for four years. Vertical angles should be tied back similar to Fig. 1.

FIG. 3.—Represents joint supporting city street traffic over yard and has given satisfactory service for four years. Details should be revised to provide anchorage. Reverse top left-hand angle to avoid long unsupported leg. Clearance between rivet heads should be provided to meet expansion requirements only.

FIG. 4.—Joints similar to that shown in Fig. 4 have been used for sidewalks of highway bridges, and have given satisfactory service for eight years. Anchorage should angle diagonally downward.

FIG. 5.—Committee does not have service record covering this joint.

FIG. 6 and 7.—These joints have given satisfactory service in highway bridges and will probably become standard practice. Although somewhat expensive, the basic principles of an expansion joint design is taken care of, a clear cut joint being provided and no sliding involved.

FIG. 8.—The reporter on joint shown in Fig. 8 comments as follows:

"The joint shown in Fig. 8 has been in service since 1928. Recent inspection has not been made and no service report covering joint available. However, it is expected this joint will work the same as other joints of this type, that is, the membrane water-proofing laid across the joint will break down within a relatively short period of time, possibly one to two years."

The Committee agrees with the expectation given above.

FIG. 9.—The reporter on joint shown at left of Fig. 9 comments as follows:

"Decks of the type shown in Fig. 9 are usually 4 inches thick and rest on closely spaced I-beams with a maximum of about 10 inches clear between flanges. As far as I know we have never installed such a deck except over a busy street or highway, so that the total length of the structure is never very great. Usually we are able to take care

of expansion at the abutment. We have used the detail shown for the abutment for a great many years, and have never had any trouble. Experience has conclusively shown, therefore, that the detail at the abutment is entirely satisfactory."

The Committee is of the opinion that the detail down the back of the abutment should be revised to provide support against puncture of the membrane after expansion takes place. Slab should be extended and water drip provided.

The expansion joint shown for use between short spans has been in service three years and has proven satisfactory. The Committee is of the opinion that the asphalt plank covering will move out of position and expose the joint.

Joint shown at the right of Fig. 9 represents a joint never built and is subject to the same criticism as the joint shown in the center.

FIG. 10.—The reporter on joint shown in Fig. 10 comments as follows:

"In general it is found that joints in which the weight of the structure is carried on a surface on which sliding is supposed to occur during expansion or contraction of the span practically never function, even when new.

"On structures having an independent bent on each side of joints and some one of numerous details for providing a continuous pavement surface by means of mastic filled spaces, show some merit, at least during the first few seasons of use, provided that great care has been used in keeping the joint absolutely clean before the mastic is introduced. From a practical standpoint this is very difficult, for on every construction job the handling and transporting of materials across the joint present great likelihood that débris of all sorts will find lodgment therein, and in the hurry to start traffic as the structure nears completion the importance of cleanliness at this point is almost sure to be overlooked.

"Assuming that a mastic filled joint has been carefully installed, the first period of hot weather forces much of the softened filler out to the surface of the pavement where it forms a ridge or is carried away by traffic. By the time cold weather causes contraction of the structure the filler has become hard and a gap opens to admit foreign matter of many kinds. After two or three such cycles there is very little of the mastic left in the joint, its place having been taken by incompressible solids. This means that the joint has become inoperative.

"It has been found that where it is not necessary to provide a joint which is waterproof the purpose is best served by some form of clear opening which is self-cleaning and can offer no resistance whatever to the movement of the structure. Whether this opening need be bridged over by interlacing fingers or whether the edges may be straight depends upon the amount of movement for which provision must be made. Details as shown in Fig. 10 have not been in use sufficiently long to furnish service data. General experience has shown that for special details of floor construction, especially at breaks in the floor of movable spans and at expansion joints, steel castings are greatly superior to structural steel assemblies. Although the latter may be lower in first cost, they rust away much more quickly and from constant vibration and impact they become loose and rattle.

"Wherever an expansion joint is provided on a structure carrying street cars it is imperative that the rails be cut at the joint and provision be made to prevent interference with the free movement of the structure."

The Committee has been advised that expansion device shown in Fig. 10 is a scheme for which patent is being applied for.

FIG. 11.—This joint has been in service for twelve years, and is a waterproof expansion joint carrying the direct roadway load. During twelve years' service no complaints have been made as to the effectiveness of the joint.

The joint is subject to heavy electrolytic action, and the under side of the structure forms the roof of a pedestrian tunnel requiring special details.

The Committee is of the opinion waterproofing should be looped over joint to prevent fracture and not laid flat.

This joint offers special details and may be used in some cases.

FIG. 12.—Represents joint for structures carrying railroad tracks and has given satisfactory service for twenty years.

FIG. 13.—This type of joint has been used to some extent and has worked satisfactorily for a number of years, but becomes troublesome and is very expensive to repair. Where possible a simpler joint is favored. In one structure in which this type of joint was used, the waterproofing was protected by a concrete covering for a block paving and considerable difficulty has been experienced due to growing of the concrete protection above the waterproofing. This growth was caused by the mass of concrete not having sufficient tensile strength to return the concrete to the length it occupies during cold weather and absolutely dry. When this action takes place, it ruins the waterproofing and the joint leaks.

FIG. 14.—This joint has been in service for approximately ten years, and has given satisfactory service.

The reporter on joint shown in Fig. 14 includes comments as follows:

"There has been no occasion to repair or refill any of these joints during the period that they have been in use. They apply to structures where there is very little movement of the adjacent units, and it is expected that they will function effectively so long as the expansion joint filler retains its original character, and so long as the waterproofing membrane is not broken.

"The detail shown in Fig. 14 shows more particularly the method adapted to insure an open space between the two adjacent units of concrete. Having this space of proper size throughout, the construction of the joint follows an old established procedure of calking the joint a couple of inches below the top with oakum, filling above the oakum with a satisfactory joint filler, and then carrying the waterproofing membrane and protection across the joint.

"This method of constructing and sealing the joint has been found satisfactory, and no such joints have been exposed for repairs during the ten years that they have been in service."

FIG. 15.—This type of joint has been used for a number of years in railway and highway concrete slab bridges, and has given satisfactory service.

FIG. 16.—Has been used on highways under heavy traffic, and has given satisfactory service. Metal sliding surface should be substituted for the tar paper.

FIG. 17.—This joint used on overhead highway bridge and was found not to give entirely satisfactory service. During hot weather the filler squeezed out of the joint forming a ridge in the roadway, making a bad riding condition. That part of the filler which was extruded wore away in cool weather, the remaining filler was not sufficient to fill the joint and permitted the entry of water.

This joint requires maintenance.

FIG. 18.—Represents a vertical joint not waterproofed in a wall supporting approaches to a viaduct. Has given two years' satisfactory service.

FIG. 19.—This is a joint used in a station platform, and similar joints have been used satisfactorily five years on highway bridges. The V-shape shown is a double loop in the copper flashing, membrane waterproofing follows the copper and is protected by the asphalt block.

FIG. 20.—This joint used under heavy traffic and has been giving satisfactory service for four years, being developed to eliminate noisy tread plates. Below are comments from report on this joint:

"Has been in service for four years, having been developed to do away with noisy tread plates. Is on main State highway carrying dense heavy traffic. Is giving good service. While the drawing from which this cut was made is of a truss bridge and the beams shown are floor beams, the revision as suggested by the Committee report would make this joint adaptable for I-beam slabs."

Revision referred to above was that bridge seat be raised to bottom of beam and sliding plate provided.

FIG. 21.—Represents a joint supporting highway traffic, and has given satisfactory service. Should be grouped with joints, Figs. 2, 3, 4 and 5.

It is recommended that the report be received as information and the subject re-assigned for further study.

## REPORT OF COMMITTEE VII—WOODEN BRIDGES AND TRESTLES

H. AUSTILL, *Chairman*;  
F. E. BATES,  
L. R. BOETTCHER,  
H. M. BUELL,  
C. R. CHEVALIER,  
H. M. CHURCH,  
F. H. CRAMER,  
W. R. EDWARDS,  
T. H. GARDNER,

S. F. GREAR,  
R. W. GUSTAFSON,  
R. P. HART,  
W. E. HAWLEY,  
C. J. HOGUE,  
W. D. KEENEY,  
J. A. NEWLIN,  
W. L. PEOPLES,  
G. W. REAR,

D. W. SMITH, *Vice-  
Chairman*;  
ARTHUR RIDGWAY,  
H. T. RIGHTS,  
W. R. ROOF,  
W. J. RYAN,  
G. C. TUTHILL,  
A. T. UPSON,  
*Committee.*

*To the American Railway Engineering Association:*

Your Committee respectfully presents herewith report covering the following subjects:

- (1) Revision of Manual.
- (2) Simplification of grading rules and classification of timber for railway uses, collaborating with other organizations concerned.
- (3) Overhead wooden or combination wooden and steel highway bridges, collaborating with Committees VIII—Masonry and XV—Iron and Steel Structures.
- (4) Design of standard wooden trestles for heavy loadings.
- (5) Bearing power of wooden piles, with recommendation as to best methods of determination, collaborating with Committee VIII—Masonry.
- (6) Best relationships between the energy of hammer and the weight or mass of pile for proper pile driving, to include concrete piles, collaborating with Committee VIII—Masonry.
- (7) Improved design of timber structures to give longer life with lower cost of maintenance.
- (8) Methods of strengthening existing bridges.
- (9) Design of washers, separators, cap-stringer straps and other trestle fastenings.

### Action Recommended

1. That proposed changes in the Manual, Appendix A, be adopted.
2. That Appendix B be received as information.
3. That Appendix C be received as information.
4. That Appendix D be received as information.
5. That Appendix E be received as information.
6. That Appendix F be received as information.
7. That Appendix G be received as information.
8. That Appendix H be received as information and the subject be discontinued.
9. That Appendix I be received as information.

Respectfully submitted,

THE COMMITTEE ON WOODEN BRIDGES AND TRESTLES,

H. AUSTILL, *Chairman.*

## Appendix A

## (1) REVISION OF MANUAL

D. W. Smith, Chairman, Sub-Committee; F. H. Cramer, W. E. Hawley, Arthur Ridgeway, G. C. Tuthill.

Your Committee recommends the following changes in the Manual:

As in the 1929 Manual

**Page 458—Relative Merits of Open and Ballast Deck Timber Trestles**

Par. 2—last line "Vastly less expensive to maintain"

Revision Recommended

Omit.

As in the 1929 Manual

**Page 458—heading "Comparative Merits of Ballast Deck and Reinforced Concrete Trestles"**

Revision Recommended

**"Comparative Merits of Creosoted Timber Ballast Deck and Reinforced Concrete Trestles"**

As in the 1929 Manual

**Page 458—Par. 5—under heading "Comparative Merits of Ballast Deck and Reinforced Concrete Trestles"**

(5) "Notwithstanding the fact that the two materials are, with certain limitations, equally suitable for the construction of trestles, the use of concrete is more in accord with the theory on conservation of natural resources and industrial economy."

Revision Recommended

Omit Par. 5, and renumber Par. 6 and Par. 7.

**Page 461**

Revision Recommended

Omit the Elevation, Plan and Detail drawing of lag screw.

As in the 1929 Manual

**Page 466—Par. 13—"Caps shall be sized and brought to a uniform thickness and even bearing on piles or posts. The side with the most sap shall be placed downward."**

Revision Recommended

Omit this paragraph.

As in the 1929 Manual

**Page 466—Par. 19—"Stringers shall be sized to a uniform depth at supports. The edges with the most sap shall be placed downward."**

Revision Recommended

Omit this paragraph.

Renumber other paragraphs on page 466.

## Appendix B

## (2) SIMPLIFICATION OF GRADING RULES AND CLASSIFICATION OF TIMBER FOR RAILWAY USES

W. E. Hawley, Chairman, Sub-Committee; H. M. Buell, C. R. Chevalier, H. M. Church, C. J. Hogue, J. A. Newlin, A. T. Upson.

Due to business conditions in which all lumber associational activities have been diverted from improvement of standards to a struggle for existence and to a new emphasis on control of competitive conditions within the lumber producing and selling organization through the opportunities presented under the National Industrial Recovery Act and the N.R.A. Codes, the work of developing standards for lumber and timber has been pushed aside to await a future time when conditions may become normal.

This Association, through this Committee, stands ready to receive all suggestions which may in any manner improve the service of timber in its various forms which are so necessary to the maintenance of the structures which are used by the railways.

The collaboration work with the Mechanical Division, A.R.A. on subject of lumber for freight cars and locomotives has been completed.

## Appendix C

## (3) OVERHEAD WOODEN OR COMBINATION WOODEN AND STEEL HIGHWAY BRIDGES

R. P. Hart, Chairman, Sub-Committee; F. H. Cramer, G. W. Gustafson, C. J. Hogue, W. D. Keeney, G. W. Rear, G. C. Tuthill.

The Committee invites attention to paragraphs 12, 13, and 14 of specifications for Timber Piles, appearing on page 470 of the 1929 Manual. The dimensions of piles specified are considered by the Committee to be larger than required for piles for use in highway overhead bridges.

The following table of dimensions for "First-Class Piles for Highway Bridges" is therefore presented.

- 14 (a) Southern pine and Douglas fir piles shall have the following limiting dimensions:

| <i>Length</i>         | <i>Diameter 3 Ft. from Butt</i> |                | <i>Diameter of Tip</i> |
|-----------------------|---------------------------------|----------------|------------------------|
|                       | <i>Minimum</i>                  | <i>Maximum</i> | <i>Minimum</i>         |
| Under 40 Ft. ....     | 12 In.                          | 16 In.         | 8 In.                  |
| 40 Ft. to 50 Ft. .... | 13 In.                          | 16 In.         | 7 In.                  |
| 50 Ft. to 60 Ft. .... | 14 In.                          | 18 In.         | 7 In.                  |
| Over 60 Feet ....     | 14 In.                          | 20 In.         | 6 In.                  |

- 14 (b) Oak of all species or cypress piles shall have the following limiting dimensions:

| <i>Length</i>         | <i>Diameter 6 Ft. from Butt</i> |                | <i>Diameter of Tip</i> |
|-----------------------|---------------------------------|----------------|------------------------|
|                       | <i>Minimum</i>                  | <i>Maximum</i> | <i>Minimum</i>         |
| Under 30 Ft. ....     | 12 In.                          | 15 In.         | 8 In.                  |
| 30 Ft. to 40 Ft. .... | 12 In.                          | 15 In.         | 7 In.                  |
| Over 40 Feet ....     | 12 In.                          | 15 In.         | 6 In.                  |

- 14 (c) Western red cedar piles shall have the following limiting dimensions:

| <i>Length</i>         | <i>Diameter 6 Ft. from Butt</i> |                | <i>Diameter of Tip</i> |
|-----------------------|---------------------------------|----------------|------------------------|
|                       | <i>Minimum</i>                  | <i>Maximum</i> | <i>Minimum</i>         |
| Under 30 Ft. ....     | 12 In.                          | 18 In.         | 8 In.                  |
| 30 Ft. to 40 Ft. .... | 13 In.                          | 20 In.         | 8 In.                  |
| Over 40 Feet ....     | 14 In.                          | 22 In.         | 7 In.                  |

The Committee also invites attention to an article, "New Type of Composite Beam", by J. F. Seiler, Engineer, Service Bureau, American Wood Preservers' Association, appearing in the November, 1933, issue of Wood Preserving News. This type of construction has been considered by the Committee in further study of its subject and may be included in plans showing recommended practice for highway overhead bridge construction now being prepared.

## Appendix D

### (4) DESIGN OF STANDARD WOODEN TRESTLES FOR HEAVY LOADING

F. E. Bates, Chairman, Sub-Committee; H. M. Church, W. R. Edwards, S. F. Grear, J. A. Newlin, G. W. Rear, W. R. Roof, W. J. Ryan, D. W. Smith.

Present plans in the Manual provide for a live load of Cooper's E-45 and E-60. A study of modern locomotives indicates loading considerably in excess of these design loads. If full life is to be secured from timber trestles, it is evident that design loading should be increased to not less than E-70. Table 1 below gives the axle loading and Cooper's rating for 14-ft. span for a few typical modern locomotives.

TABLE 1—TYPICAL MODERN LOCOMOTIVES

| Railroad               | Type    | Locomotive                |                          | Cooper's Class  |               | Tender            |
|------------------------|---------|---------------------------|--------------------------|-----------------|---------------|-------------------|
|                        |         | Average Driving Axle Load | Driving Axle Spacing Ft. | 14' Span Moment | Bent reaction | Average Axle Load |
| Western Maryland ..... | 2-10-0  | 77,400                    | 5.62                     | E-69            | E-77          | 69,300            |
| Northern Pacific ..... | 2-8-8-4 | 70,000                    | 5.62                     | E-61            | E-66          | 67,000            |
| C.B.&Q. ....           | 2-10-4  | 70,700                    | 5.58                     | E-63            | E-71          | 64,000            |
| A.T.&S.F. ....         | 2-10-4  | 70,000                    | 6.17                     | E-59            | E-63          | 63,000            |
| Western Pacific .....  | 2-8-8-2 | 69,100                    | 5.50                     | E-63            | E-63          | 68,000            |
| Lehigh Valley .....    | 4-8-4   | 67,500                    | 6.42                     | E-55            | E-61          | 61,000            |
| C.B.&Q. ....           | 4-8-4   | 68,500                    | 6.42                     | E-53            | E-55          | 58,500            |
| Missouri Pacific ..... | 2-8-4   | 69,000                    | 5.62                     | E-61.6          | E-65          | 54,000            |

Attention is called to the axle loading for the locomotive tenders and it will be noted that in many cases they are practically equal to the load on the drivers. Axle spacing in the typical 6-wheel tender trucks is from 50 to 60 inches and for short span lengths such as are used in timber trestle construction the stresses in the stringers are higher under the tender load than under the driver load. Driver loading equal to or exceeding 70,000 lb. per axle is quite common but the increase in axle spacing required for the larger diameter drivers holds Cooper's classification below E-70 for panel lengths 12 to 16 ft.

Table 2 gives a comparison of unit stresses for a selected number and size of stringers for open and ballasted deck. Attention is called to the two methods of computing horizontal shear in the stringers. The Forest Products Laboratory at Madison, Wis., has made an extensive series of tests to determine horizontal shear stresses and their distribution in the beam. Results of these tests were published in the Engineering News-Record dated May 11, 1933. J. A. Newlin, a member of this Committee, has prepared a statement giving results of these tests which appears in Exhibit A. It will be noted that empirical formula used to derive horizontal shear stresses in a beam gives results somewhat in excess of actual stresses as determined by test.

## Exhibit A

## SHEAR IN CHECKED BEAMS

By J. A. NEWLIN, In Charge Section of Timber Mechanics

Forest Products Laboratory,<sup>1</sup> Forest Service, U. S. Department of Agriculture

This paper is intended to supplement an article on the same subject<sup>2</sup> published in a recent issue of Engineering News-Record by developing an analysis by which the recommended empirical assumptions as to loading may be checked.

In the article referred to it was stated that both from theoretical consideration and from tests the reaction to cause failure by shear could be divided into two parts. The first part, which was there designated as  $B$  but is here termed  $r_1$  was shown to be independent of the position of the load. The second term, designated here as  $r_2$ , was defined as varying inversely with the distance of the load from the support. The term  $r_1$  represents that part of the total reaction which is associated with shear in the neutral plane and  $r_2$  the part of the total reaction that is carried by the upper and lower parts of the beam acting as two independent beams. It was pointed out that  $r_1$  is the value used in the ordinary shear formula to represent the total reaction.

The above load partition may be expressed algebraically as

$$(1) \quad \frac{r_2}{r_1} = \frac{C}{x^2}$$

where  $x$  is the distance of the load from the support. If in this equation  $x$  is expressed in absolute units such as inches, then  $C$  is dependent upon the height of the beam; but if

$$x = \frac{\text{inches from support}}{\text{height of beam in inches}}$$

as taken, then test data show that  $C$  becomes practically a constant for beams of various sizes and degrees of checking from moderate to severe. It is necessary in the further development to assume that equation (1) is true for loads less than those which will cause failure by shear. This assumption appears reasonable, since even at failure the action of the beam is elastic except for a very local area at the bottom of the checks.

The value of  $C$  in equation (1) is found from test data to be 2. Substituting this value in equation (1), we have

$$(2) \quad \frac{r_2}{r_1} = \frac{2}{x^2}$$

If  $P$  is taken as the concentrated load for which  $r_1$  and  $r_2$  are the two parts of the reaction, then

$$(3) \quad r_1 + r_2 = \frac{P(L-x)}{L}$$

Hence, from (2) and (3).

$$(4) \quad r_1 = \frac{P(L-x)x^2}{L(2+x^2)}$$

(Both  $L$  and  $x$  being in terms of height of beam, it is necessary to know the height of the beam before  $r_1$  can be found.)

The position of  $P$  which is most likely to cause shear failure, or, in other words, at which  $r_1$  is a maximum, may be obtained by equating the first derivative of  $r_1$  with respect to  $x$  in equation (4) to zero. This yields the equation

$$(5) \quad 4L - 6x - x^3 = 0.$$

With all values of  $L$  from 12 to 21,  $x$  will be found to be between 3 and 4.

<sup>1</sup> Maintained at Madison, Wis., in cooperation with the University of Wisconsin.

<sup>2</sup> "Wood Beam Design Method Promises Economies," by J. A. Newlin, G. E. Heck, and H. W. March. May 11, 1933.

An equation for uniform load may be developed from equation (4) by replacing  $P$  by  $Wdx$ , where  $W$  is the load per unit of length and  $dx$  is the differential of length, and replacing  $r_1$  by  $dr_1$ , the differential of reaction associated with shear corresponding to the load  $Wdx$ . Thus,

$$(6) \quad dr = \frac{W(L-x)x^2}{L(2+x^2)} dx$$

Integrating this equation and determining the constant of integration by making  $r_1 = 0$  when  $x = 0$ , we obtain

$$(7) \quad r_1 = \frac{W(L - \frac{x}{2})x}{L} - \frac{W}{L} \left[ \sqrt{2} L \tan^{-1} \frac{x}{\sqrt{2}} - \log_e (2 + x^2) + \log_e 2 \right]$$

If  $x$  is replaced by  $L$  in the above equation, we have a uniform load over the entire beam. By this substitution and a slight simplification, the following equation is obtained:

$$(8) \quad r_1 = \frac{WL}{2} - \left[ \sqrt{2} W \tan^{-1} \left( \frac{L}{\sqrt{2}} \right) - \frac{W}{L} 2.3 \log_{10} \left( \frac{2 + L^2}{2} \right) \right]$$

In this equation the first term of the right-hand member is the reaction as usually calculated, and the terms in brackets represent the two-beam portion of the reaction. It will be noted that for moderate to long spans the first term in the bracket is almost constant, increasing very slowly with increase in span. The last term is small as compared with the preceding term, and since it contains  $L^2$  in the logarithmic portion and  $L$  as a divisor, it will continually decrease as  $L$  increases. Within practical limits of span and beam heights this uniform load equation is approximated so closely by

$$(9) \quad r_1 = \frac{9}{10} W \left( \frac{L}{2} - 1 \right),$$

that we could recommend the use of equation (9) to the exclusion of equation (8).

Fig. 1 is a graphical representation of the total, single-beam, and two-beam reaction for a beam with a span-height ratio of 12. For a single concentrated load the ordinates to the straight line represent the total reaction; "a" the ordinate in the cross-hatched portion is the single-beam reaction, associated with shear in the neutral plane. The two-beam reaction is represented by "b", that part of the ordinate in the unshaded area. Placing the load at 3.1 times the height of the beam from the support gives the maximum single-beam reaction and is the point at which to place the load for greatest likelihood of failure by shear. For a uniform load over the entire span, the area under the straight line represents the total reaction, the cross-hatched area, the single-beam reaction, and the unshaded area that portion of the reaction which is carried to the support by two-beam action and is not associated with shear in the neutral plane.

For spans longer than 12, the unshaded area increases only slowly, while the shaded area increases a little more rapidly than the span, and the maximum point of the shaded area moves to the right; but at a span-height ratio of 20 the maximum point is still a little short of four times the height of beam from the support.

The ultimate load at which failure in a checked bridge stringer may be expected can be estimated with fair accuracy from the shearing stress as obtained in standard shear block tests by the use of the above formulas (4) and (9), by estimating the percent-

age of unchecked area to total area at or near the neutral plane between the support and a point located at three times the height of the beam from the support and taking

$\frac{4}{9}$  of the stress as obtained by the standard shear test as the expected stress. The  $\frac{4}{9}$

is a factor which represents the reduction in average or mean stress at failure due to concentration of stress at the bottom of the checks. This figure is about right for the ordinary seasoned bridge stringer with unequal depths of checking on the two faces.

REACTION DIAGRAM  
FOR A  
SPAN HEIGHT RATIO OF 12

The use of the above equations in determining the reactions to be used in the ordinary shear formula for rectangular beams and safe stresses as previously published requires the inclusion of a  $\frac{10}{9}$  factor in the formulas because of the fact that there was approximately 10 per cent of two-beam reaction in the tests from which the safe stresses were derived.

The following recommendations assume the use of equation (9) for uniform load, and equation (4) whenever a fairly exact shearing strength of a beam is required.

### Recommendations

1. Use the ordinary shear formula and the safe stresses previously published.
2. In figuring the reactions,
  - (a) neglect all loads within the height of the beam from both supports.
  - (b) place the heavy concentrated moving load at three times the height of the beam from the support.
  - (c) treat all other loads in the usual manner.
3. If a timber does not qualify under the above recommendations which under certain conditions may be over-conservative, the reactions for the concentrated loads should be checked by the following equation:

$$(10) \quad r^1 = \frac{10P^1(L^1 - x^1) \left(\frac{x^1}{h}\right)^2}{9L^1 \left\{ 2 + \left(\frac{x^1}{h}\right)^2 \right\}}$$

in which

$r^1$  is the reaction to be used as due to a load  $P^1$ .

$L^1$  = span in inches.

$x^1$  = distance in inches from the reaction to the load  $P^1$ .

$h$  = height of beam in inches.

Equation (10) is derived from equation (4) by including a factor of  $\frac{10}{9}$  to make it suitable for use with the previously published stresses and a change of  $L$  and  $x$  from dimensional units to inches.

### Appendix E

#### (5) BEARING POWER OF WOODEN PILES, WITH RECOMMENDATION AS TO BEST METHODS OF DETERMINING

W. R. Edwards, Chairman, Sub-Committee; L. R. Boettcher, H. M. Buell, W. D. Keeney, G. W. Rear, W. J. Ryan, G. C. Tuthill.

The Committee has found it impossible to advance this year the studies previously made.

### Appendix F

#### (6) BEST RELATIONSHIPS BETWEEN THE ENERGY OF HAMMER AND THE WEIGHT OR MASS OF PILE FOR PROPER PILE DRIVING TO INCLUDE CONCRETE PILES

C. R. Chevalier, Chairman, Sub-Committee; T. H. Gardner, R. W. Gustafson, W. D. Keeney, W. L. Peoples, H. T. Rights, W. J. Ryan.

The Committee has found very little data available, as the records of test pile driving do not furnish the weights of piles because generally tests are made to determine the proper length of pile and its actual supporting power at the place where a foundation is to be constructed.

The Committee recommends that actual tests should be made by driving both wood and concrete piles to refusal, at the same location. Using three weights of hammers and proper driving records kept showing weight of piles. Then the piles loaded until equal settlement occurs.

Attention is invited to Bulletin 36 (pages 74 to 85) Public Works of the Navy, reporting the driving and loading of test piles at the Naval Supply Depot, San Diego, Cal.

## Appendix G

### (7) IMPROVED DESIGN OF TIMBER STRUCTURES TO GIVE LONGER LIFE WITH LOWER COST OF MAINTENANCE

F. H. Cramer, Chairman, Sub-Committee; F. E. Bates, L. R. Boettcher, H. M. Buell, H. M. Church, S. F. Gear, J. A. Newlin, W. L. Peoples, A. T. Upson.

The Committee has made an extensive study of the subject and has accumulated data that it expects to develop into a worthwhile report at a later date, but for the present can only report progress.

## Appendix H

### (8) METHODS OF STRENGTHENING EXISTING BRIDGES

S. F. Gear, Chairman, Sub-Committee; W. R. Edwards, T. H. Gardner, R. P. Hart, W. L. Peoples, H. T. Rights, W. R. Roof.

In preparing this report, it is assumed that the intent is to outline methods of changing structures to a heavier type and not to cover ordinary repairs. This will cover only wooden trestles.

The strengthening of old structures should be done in a manner to bring them as nearly as possible to the established standard for the district.

Standard materials must be used to the fullest possible extent to avoid the necessity of carrying special sizes for repairs.

In general, treated and untreated materials must not be mixed in the same structure.

Any additional piles or posts placed in a bent should be placed as closely as possible under the rails. This puts the new bearing where it gets the direct load and where it strengthens the existing cap.

When additional stringers are necessary, the old stringers must be loosened and re-spaced so that the stringers as a unit are symmetrical about the center line of the rail. New stringers must be bolted to the old stringers.

Cross-bracing must be changed so that it will be fastened to the new members of the bent.

Any bolt holes left in treated material must be swabbed with hot creosote oil and filled with treated plugs; any cut surfaces in treated material must be painted with hot creosote oil.

The above methods will, in general, preclude the necessity of putting in heavier caps and ties.

Where strengthening is due to cause other than design, different methods are required.

A frequent source of trouble is the lack of proper bearing power of piles. This condition may be remedied, in some cases, by posts on sills but this is a makeshift and is to be considered only as a temporary arrangement.

Where waterway conditions permit, helper bents will strengthen both the bents and stringers and can generally be so spaced as to become part of a replacement structure.

Trestles which must be raised to have three or more caps should have outside batter piles driven in line with each bent, and the top cap made long enough to reach the tops of these batter piles. These piles serve to stiffen the trestle both laterally and longitudinally. Bracing must be changed so as to be attached to all caps.

Greater stability can be obtained by the use of diagonal bracing placed horizontally from cap to cap just under the stringers.

When additional piles in the line of the bent are required to carry the load, double caps must be used where necessary to distribute the load.

### Conclusion

It is the recommendation that this report be received as information and the work of the Sub-Committee be discontinued.

### Appendix I

#### (9) DESIGN OF WASHERS, SEPARATORS, CAP-STRINGER STRAPS, AND OTHER TRESTLE FASTENINGS

R. W. Gustafson, Chairman, Sub-Committee; L. R. Boettcher, T. H. Gardner, R. P. Hart, H. T. Rights, W. R. Roof.

Plans of standard timber trestles and standard trestle fastenings have been received from twenty-three of the larger railroads for the purpose of studying the various designs now used.

We find a number of different methods and details of fastenings being used, although certain details are common on the majority of the roads. The most common details used are as follows:

1. Outer guard-timber is notched and bolted to ties.
2. Ties are boat spiked to stringers.
3. Stringers are drift bolted to caps.
4. Caps are drift bolted to piles.
5. Cast iron separators are used between stringers—type varies.
6. Cast iron O.G. washers are used.
7. Bracing is bolted to piles.

We feel that some of the details are used merely because they have been standard on the system for a long time.

This Sub-Committee will prepare designs of washers, separators, and fastenings with the following points in mind.

(1) The design of trestle fastenings should be as simple as possible and as few in number as is consistent with good practice and safety.

(2) Washers and separators should be simple in design and efficient but of minimum weight to reduce cost.

(3) Fastenings should be designed so that a minimum amount of moisture can get to the inner fibers of the timber and thus reduce rotting.

Sketch A shows a preliminary design of a separator and a method of fastening stringers to caps without the use of drift bolts. Criticism and suggestions are invited from the Association.

Sketch A  
Showing a Method of Fastening Stringers  
to Caps. To Avoid Use of Drift Bolts

Sketch B shows alternate designs which may be used to avoid the use of drift bolts in stringers. The Committee feels that the old custom of using drift bolts in stringers, particularly in untreated timber, is a practice that should be discontinued.

Sketch C shows preliminary designs of a cast iron washer, a malleable washer, a packing spool using two C.I. washers, and a method of fastening stringers to caps.

*Committee.*

*To the American Railway Engineering Association:*

Your Committee respectfully presents herewith report covering the following subjects:

(1) Revision of Manual, including Specifications for Steel Railway Bridges, first edition (Appendix B). It is recommended that these Specifications be received as information.

(3) Tests of steel columns and formulae for design (Appendix A).

(5) Use of alloy steels for structural purposes (Appendix A).

(6) Impact—railway bridges (Appendix A).

(7) Bearing values of small rollers (Appendix A).

On the other subjects in our assignment, namely, Nos. 2, 8, 9, 11, 12, and 13 we report progress.

Respectfully submitted,

THE COMMITTEE ON IRON AND STEEL STRUCTURES,

A. R. WILSON, *Chairman*.

### Appendix A

#### (3) TESTS OF STEEL COLUMNS AND FORMULAE FOR DESIGN

J. B. Hunley, Chairman, Sub-Committee; A. W. Carpenter, Hardy Cross, O. E. Hovey, P. B. Motley, F. E. Turneure.

#### (5) USE OF ALLOY STEEL FOR STRUCTURAL PURPOSES

C. H. Mercer, Chairman, Sub-Committee; G. A. Haggander, Adolph J. Buhler, R. P. Davis, S. Hardesty, O. E. Hovey, J. B. Hunley, Jonathan Jones, H. C. Tammen.

#### (6) IMPACT—RAILWAY BRIDGES

F. E. Turneure, Chairman, Sub-Committee; J. E. Bernhardt, Adolph J. Buhler, C. H. Chapin, Hardy Cross, O. F. Dalstrom, R. P. Davis, F. O. Dufour, O. E. Hovey, J. B. Hunley, W. S. Lacher, B. R. Leffler, C. H. Mercer, I. L. Simmons, C. E. Sloan, S. M. Smith, W. M. Wilson.

**(7) BEARING VALUES OF SMALL ROLLERS**

W. M. Wilson, Chairman, Sub-Committee; O. F. Dalstrom, O. E. Hovey, B. R. Leffler.  
P. B. Motley, O. E. Selby, F. P. Turner, R. A. Van Ness.

The reports of these four sub-committees are included in the Specifications for Steel Railway Bridges, Appendix (B).

**Appendix B****(1) REVISION OF MANUAL****SPECIFICATIONS FOR STEEL RAILWAY BRIDGES****For Fixed Spans not Exceeding 400 Feet in Length**

FIRST EDITION—MARCH, 1934

It is recommended that these Specifications be received as information.

| 7. Will end floor beams be required? .....                                                         | 108     |

# SPECIFICATIONS FOR STEEL RAILWAY BRIDGES\*

For Fixed Spans Not Exceeding 400 Feet in Length

---

## PART I—DESIGN AND MANUFACTURE

### SECTION A—PROPOSALS AND DRAWINGS

#### Definition of Terms

1. The term "Company" means the Railway Company party to the contract. The term "Engineer" means the Chief Engineer of the Company or his subordinates in authority. The term "Inspector" means the inspector representing the Company. The term "Contractor" means the manufacturing or fabricating contractor party to the contract.

#### Proposals

2. Bidders shall submit proposals conforming to the terms in the letter of invitation. The proposals preferably shall be based on plans and specifications furnished by the Company. Such plans will show the conditions determining the design of the bridge, the general dimensions, stresses, and typical details.

Invitations requiring the Contractor to furnish the design will state the general conditions at the site, such as track spacing, character of foundation, presence of old structures, traffic conditions, etc.

#### Shop Drawings

3. After the contract has been awarded and before the work is begun, the Contractor shall submit to the Engineer for approval, prints in duplicate of the stress sheets and shop drawings, unless such drawings shall have been prepared by the Company.

Shop drawings shall be made in ink on the dull side of the tracing cloth, 24 by 36 inches in size, including margins. The margin at the left end shall be  $1\frac{1}{2}$  inches wide, and the others  $\frac{1}{2}$  inch. The title shall be in the lower right-hand corner.

No change shall be made on any approved drawing without the consent, in writing, of the Engineer.

The tracings of the drawings shall be the property of, and be delivered to, the Company after the completion of the contract.

4. The Contractor shall be responsible for the correctness and completeness of his drawings, although the drawings may have been approved by the Engineer.

5. If material is ordered by the Contractor before the drawings have been approved, the Contractor shall assume the risk.

#### Drawings to Govern

6. If the drawings and the specifications differ, the drawings shall govern.

#### Patented Devices

7. The Contractor shall protect the Company against claims arising from the use of patented devices or parts proposed by him.

---

\* The Specifications for Movable Railway Bridges of the American Railway Engineering Association, 1922, and current revisions thereof govern those features of movable bridges not covered by these specifications.

### Notice to Engineer

8. No material shall be rolled or work done before the Engineer has been notified where the orders have been placed.

## SECTION 1—GENERAL FEATURES OF DESIGN

### Materials

101. Structures shall be made wholly of structural steel except where otherwise specified. Rivet steel shall be used for rivets only. Forged steel shall be used for large pins, large expansion rollers, and other parts if specified by the Engineer. Cast steel preferably shall be used for shoes, rockers, and bearings. Cast iron may be used only where specifically authorized by the Engineer.

### Types of Bridges

102. The types of bridges to be used for various span lengths may be as follows:

Rolled beams for spans up to 40 feet.

Plate girders for spans up to 125 feet.

Riveted trusses for spans 100 feet or longer.

Pin-connected trusses for spans 150 feet or longer.

### Spacing of Trusses, Girders, and Stringers

103. The distance between centers of trusses or girders shall be sufficient to prevent overturning by the specified lateral forces. In no case shall it be less than one-twentieth of the span for trusses, nor one-fifteenth of the span for girders.

The girders of deck spans and the stringers of through spans shall be spaced not less than 6 feet 6 inches between centers. If four stringers or girders are used under one track they shall be arranged in pairs, one pair symmetrical about each rail.

### Depth Ratios

104. The depth of trusses preferably shall be not less than one-tenth of the span. The depth of plate girders preferably shall be not less than one-twelfth of the span. The depth of rolled beams used as girders and the depth of solid floors preferably shall be not less than one-fifteenth of the span. If smaller depths are used, the sections shall be so increased that the deflection will not be greater than if these limiting depth ratios were not exceeded.

### Clearances

105. The clearances on straight track shall not be less than those shown in Fig. 1. On curved track the clearance shall be increased to allow for the overhanging and the tilting of a car 80 feet long, 60 feet between centers of trucks, and 14 feet high.

The superelevation of the outer rail shall be as specified by the Engineer. The distance from the top of rail to the top of tie shall be taken as 8 inches. Where legal requirements provide greater clearances, they shall govern.

FIG. 1

## Dimensions for Calculation

106. For the calculation of Stresses:

The length shall be:

For trusses and girders, the distance between centers of bearings.

For floor beams, the distance between centers of trusses or girders.

For stringers, the distance between centers of floor-beams.

The depth shall be:

For pin-connected trusses, the distance between centers of pins.

For riveted trusses, the distance between centers of gravity of chords.

## Ambiguity of Stress

107. Bridges shall be so designed as to avoid, as far as practicable, ambiguity in the determination of the stresses.

## End Floor Beams

108. Spans with floor systems shall have end floor beams unless otherwise specified. End floor beams shall be proportioned for lifting the span without exceeding the design unit stresses more than 50 per cent.

## Skew Bridges

109. At the ends of skew bridges, the ends of the supports for each track shall be square with the line of the track.

## Floor

110. Ties shall be not less than ten feet long, and spaced not more than six inches apart. They shall be secured against bunching.

## SECTION 2—LOADS AND STRESSES

### Loads and Forces

201. Bridges shall be proportioned for the following loads and forces:

- (a) Dead Load.
- (b) Live Load.
- (c) Impact.
- (d) Centrifugal force.
- (e) Other lateral forces.
- (f) Longitudinal force.

Stresses from each of these loads and forces shall be shown separately on the stress sheet.

### Dead Load

202. In estimating the weight for the purpose of computing dead load stresses, the following unit weights shall be used:

|                                             | <i>Pounds per<br/>Cubic Foot</i> |
|---------------------------------------------|----------------------------------|
| Steel .....                                 | 490                              |
| Concrete .....                              | 150                              |
| Sand, gravel, and ballast .....             | 120                              |
| Asphalt-mastic and bituminous macadam ..... | 150                              |
| Granite .....                               | 170                              |
| Paving bricks .....                         | 150                              |
| Timber .....                                | 60                               |

The track rails, inside guard rails, and fastenings shall be assumed to weigh 200 pounds per linear foot for each track.

### Live Load

203. The recommended live load for each track is the E-72 load shown in Fig. 2 and 3.

FIG. 2

FIG. 3.

The Engineer shall specify the live load to be used, such load to be proportional to the recommended load, with the same axle spacing.

For bridges on curves, provision shall be made for the increased proportion carried by any truss, girder, or stringer due to the eccentricity of the load.

For members receiving load from more than one track, the proportions of full live load on the tracks shall be as follows:

For two tracks, full live load.

For three tracks, full live load on two tracks and one-fourth on the other track.

For four tracks, full live load on two tracks, one-half on one track, and one-fourth on the remaining one.

The selection of the tracks for these proportions shall be such as will give the greatest live load stress.

### Distribution of Live Load

203a. Floor beams that are spaced close enough to carry the track loads without stringers shall be designed for a proportion of the axle load equal to the ratio of the floor beam spacing to the axle spacing. The floor beams shall be connected by solid-web diaphragms at intervals not exceeding 12 times the flange width, with at least one diaphragm for each track.

203b. For ballasted floor bridges, the lateral distribution of the live load shall be taken as uniform over a width of 14 feet but not exceeding the distance between centers of tracks.

### Impact

204. To the maximum computed static live load stresses, there shall be added the impact, consisting of:

(a) The rolling or lurching effect:

A percentage of the static live load stress equal to  $\frac{100}{S}$

$S$  = spacing, in feet, between centers of longitudinal girders, stringers, or trusses; or length, in feet, of floor beams or transverse girders.

(b) The dynamic effect:

For steam locomotives (hammer blow, track irregularities, and car impact), a percentage of the static live load stress equal to:

Spans less than 100 feet in length..... $100-0.60L$

Spans 100 feet or more in length..... $\frac{1800}{L-40} + 10$

For electric locomotives (track irregularities and car impact),

a percentage of the static live load stress equal to .....  $\frac{360}{L} + 12.5$

$L$  = length, in feet, center to center of bearings, for longitudinal stringers, girders, or trusses;

or,  $L$  = length of floor beams or transverse girders, in feet, for floor beams, floor beam hangers, and transverse girders.

The impact shall not exceed 100 per cent. of the static live load.

For members receiving load from more than one track, the impact percentage shall be applied to the static live load on the number of tracks shown below:

*Loads received from*

*Two tracks*

*Impact applied to*

$L$  = less than 175 feet ..... Two tracks

$L$  = 175 feet or more ..... One track

More than two tracks ..... Any two tracks

### Centrifugal Force

205. On curves the centrifugal force (assumed to act 6 feet above the rail) shall be taken equal to a percentage of the live load, including impact, according to the following table.

| Degree of Curve            | 0°<br>20' | 0°<br>40' | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 |
|----------------------------|-----------|-----------|----|----|----|----|----|----|----|----|----|----|----|----|
| Speed in miles<br>per hour | 80        | 80        | 80 | 65 | 53 | 46 | 41 | 38 | 35 | 33 | 31 | 29 | 28 | 27 |
| Percentage                 | 2½        | 5         | 7½ | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 |

### Wind on Loaded Bridge

206. The wind force shall be considered as a moving load acting in any horizontal direction. The wind force on the bridge shall be taken at 30 pounds a square foot of:

(a) one and one-half times the floor system and girders as seen in elevation.

(b) the vertical projection of all trusses.

but not less than 200 pounds a linear foot of loaded chord and 150 pounds a linear foot of unloaded chord.

The wind force on the train shall be taken as 300 pounds a linear foot on one track, applied 8 feet above the top of the rail.

### Wind on Unloaded Bridge

207. If a wind force of 50 pounds a square foot of surface as defined above, on the unloaded bridge, would produce greater stresses than the wind forces specified in Article 206 combined with the live load, the members where such greater stresses occur shall be designed therefor.

### Stability of Spans and Towers

208. In calculating the stability of spans and towers, they shall be considered as loaded on one track with empty cars weighing 1200 pounds a linear foot, and subjected

to a wind force of 300 pounds a linear foot applied 8 feet above the top of the rail. On multiple track bridges, this load shall be on the leeward track.

### **Sway of Engines**

209. The lateral force to provide for the effect of the sway of engines, in addition to the wind loads specified, shall be a moving concentrated load of 20,000 pounds applied at the top of rail, in either horizontal direction, at any point of the span.

### **Transverse Shear between Compression Members**

210. The lateral bracing between the compression chords or flanges of trusses and girders and between the posts of viaduct towers shall be proportioned for a transverse shear in any panel equal to  $2\frac{1}{2}$  per cent. of the total axial stress in both members in that panel, in addition to the shear from the specified lateral forces.

### **Longitudinal Force**

211. The longitudinal force resulting from the starting and stopping of trains shall be the larger of:

- (a) Force due to braking.

Fifteen per cent. of the live load reaction on the tower without impact, but not less than 350 pounds per foot of track.

- (b) Force due to traction.

Twenty-five per cent. of the weight on the driving wheels, without impact.

The longitudinal force shall be taken on one track only and shall be assumed to act 6 feet above the top of the rail.

For bridges where, by reason of continuity of members or frictional resistance, much of the longitudinal force will be carried direct to the abutments, such as ballasted deck bridges of only three or four spans, the longitudinal force shall be taken as one-half that specified above.

### **Reversal of Stress**

212. Members subject to reversal of stress shall be designed to resist each kind of stress including impact. The stress for designing the connections shall be that obtained by taking the resultant stress of each kind, tension and compression, including impact, and adding 50 per cent. of the smaller stress to the larger.

### **Combined Stresses**

213. Members subject to both axial and bending stresses (including bending due to floor-beam deflection) shall be so proportioned that the combined fiber stresses will not exceed the allowed axial stress. In members continuous over panel points, only three-fourths of the bending stress computed as for simple beams shall be added to the axial stress.

214. Members subject to stresses produced by a combination of dead load, live load, centrifugal force, and impact, with either lateral or longitudinal forces, or with bending due to lateral or longitudinal forces, may be proportioned for unit stresses 25 per cent. greater than those specified in Article 301; but the section of the member shall be not less than that required for the combination of dead load, live load, centrifugal force, and impact.

### **Secondary Stresses**

215. The design and details shall be such that secondary stresses will be as small as practicable. Secondary stresses due to truss distortion need not be considered in any

member the width of which, measured parallel to the plane of the truss, is less than one-tenth of its length. If the secondary stress exceeds 4,000 pounds per square inch for tension members and 3,000 for compression members, then the excess over 4,000 pounds per square inch for tension members and 3,000 for compression members, shall be treated as a primary stress.

## SECTION 3—UNIT STRESSES

## Unit Stresses

301. The allowable unit stresses to be used in proportioning the parts of a bridge shall be as follows:

|                                                                                                                              | <i>Pounds Per<br/>Square Inch</i>      |
|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| (a) <b>Structural and Rivet Steel.</b>                                                                                       |                                        |
| Axial tension, structural steel, net section .....                                                                           | 18,000                                 |
| Stress in extreme fibers of rolled shapes, girders, and built sections, subject to bending, net section .....                | 18,000                                 |
| Axial compression, gross section, for values of $\frac{l}{r}$ not greater than 140: (See note).                              |                                        |
| For riveted ends .....                                                                                                       | $15,000 - \frac{1}{4} \frac{l^2}{r^2}$ |
| For pin ends .....                                                                                                           | $15,000 - \frac{1}{8} \frac{l^2}{r^2}$ |
| $l$ = length of member, in inches.<br>$r$ = least radius of gyration of member, in inches.                                   |                                        |
| Compression in flanges of rolled beams and plate girders, for values of $\frac{l}{b}$ not greater than 40.....               | $18,000 - 5 \frac{l^2}{b^2}$           |
| $l$ = length, in inches, of unsupported flange between lateral connections or knee braces.<br>$b$ = flange width, in inches. |                                        |
| Stress in extreme fibers of pins .....                                                                                       | 27,000                                 |
| Shear in plate girder webs, gross section .....                                                                              | 11,000                                 |
| Shear in power-driven rivets and pins .....                                                                                  | 13,500                                 |
| Shear in turned bolts and hand-driven rivets .....                                                                           | 11,000                                 |
| Bearing on power-driven rivets, pins, outstanding legs of stiffener angles, and other steel parts in contact .....           | 27,000                                 |

NOTE.—For values of  $\frac{l}{r}$  greater than 140 and for columns of known eccentricity, see Appendix A.

|                                                                                              |        |
|----------------------------------------------------------------------------------------------|--------|
| Rivets driven by pneumatically or electrically operated hammers are considered power-driven. |        |
| Bearing on rocker pins .....                                                                 | 9,000  |
| Bearing on turned bolts and hand-driven rivets .....                                         | 20,000 |
| Bearing on expansion rollers and rockers, pounds per linear inch .....                       | $600d$ |
| $d$ = diameter of roller or rocker, in inches.                                               |        |

## (b) Cast Steel.

For cast steel shoes and pedestals, the allowable unit stresses for structural steel shall apply.

(c) **Masonry.**

Bearing pressure:

|                               |       |
|-------------------------------|-------|
| Granite .....                 | 1,000 |
| Sandstone and limestone ..... | 500   |
| Concrete .....                | 750   |

**Effective Diameter of Rivets**

302. The nominal diameter of rivets shall be considered the effective diameter.

**Effective Bearing Area**

303. The effective bearing area of pins, bolts, and rivets shall be the diameter multiplied by the length in bearing; except that for countersunk rivets, half the depth of the countersink shall be deducted.

**Slenderness Ratio**

304. The slenderness ratio (ratio of length to least radius of gyration) shall not exceed:

- 100 for main compression members.
- 120 for wind and sway bracing in compression.
- 140 for single lacing.
- 200 for double lacing.
- 200 for tension members other than eye bars.

**SECTION 4—DETAILS OF DESIGN****Thickness of Material**

401. Metal, except for fillers, shall be not less than  $\frac{3}{8}$  inch thick. Parts subject to marked corrosive influences shall be of greater thickness than otherwise or else protected against such influences.

The thickness of gusset plates connecting the chords and web members of a truss shall be proportionate to the stress to be transferred but not less than  $\frac{1}{2}$  inch.

**Accessibility of Parts**

402. Details shall be such that all parts will be accessible for inspection, cleaning, and painting. Closed sections shall be avoided wherever possible.

**Drainage of Pockets**

402a. Pockets or depressions that would hold water shall have effective drain holes or else be filled with concrete or other suitable material.

**Eccentric Connections**

403. Eccentric connections shall be avoided if practicable, but if they are unavoidable the members shall be so proportioned that the combined stresses will not exceed the allowable axial stress. Members shall be so arranged that their gravity axes will intersect in a point.

**Compression Members**

404. Built-up compression members shall be so designed that the main elements of the section will be connected directly to the gusset plates, pins, or other members.

The center of gravity of the section shall coincide as nearly as practicable with the center line of the section. Preferably the segments shall be connected by solid webs.

In members consisting of segments connected by cover plates or lacing, or segments connected by webs, the thickness of the webs of the segments shall be not less than

1/30 of the unsupported distance between the nearest rivet lines or the roots of the flanges of rolled segments. The thickness of the cover plates or webs connecting the segments shall be not less than 1/40 of the unsupported distance between the nearest lines of their connecting rivets or the roots of their rolled flanges.

### Outstanding Legs of Angles

405. The width of the outstanding legs of angles in compression, except those reinforced by plates, shall not exceed the following:

- (a) For stringer flange angles, ten times the thickness.
- (b) For main members carrying axial stress, twelve times the thickness.
- (c) For bracing and other secondary members, fourteen times the thickness.

### Rigid Members

406. The first and second panels of the bottom chords at each end of single track pin-connected truss spans, and the hip verticals and members with similar functions in all spans shall be rigid.

### Strength of Connections

407. Connections shall have a strength not less than that of the member connected, based on the allowable unit stress in the member; except that for longitudinal, transverse, and sway bracing members, the strength of the connections shall be not less than 70 per cent. of the strength of the member nor less than the calculated stress. Connections shall be made as nearly symmetrical as practicable about the axes of the members.

### Net Section

408. The width for computing the net section of riveted tension members shall be the least width that can be obtained, for any straight or zig-zag chain of holes, by deducting from the gross width an amount:

$$h + \Sigma w$$

the values of  $w$  being given by the formula:

$$w = h - \frac{s^2}{4g}$$

$h$  = diameter of rivet holes, in inches.

$s$  = pitch of any two contiguous holes in the chain, in inches.

$g$  = gage of the same two holes, in inches.

$w$  = width, in inches, to be deducted for that gage.

If the value of  $w$  is negative no deduction shall be made for that gage.

The diameter of the hole shall be taken as  $\frac{1}{8}$  inch greater than the nominal diameter of the rivet.

### Effective Sections of Angles

409. If angles in tension are so connected that bending cannot occur in any direction, the effective section shall be the net section of the angle. If connected on one side of a gusset plate, the effective section shall be the net section of the connected leg plus one-half the section of the unconnected leg.

### Section at Pin Holes

410. In pin-connected riveted tension members the net section beyond the pin hole, parallel with the axis of the member, shall be not less than the net section of the member. The net section through the pin hole, transverse to the axis of the member, shall be at least 40 per cent. greater than the net section of the member.

### Grip of Rivets

411. If the grip of rivets carrying calculated stress exceeds four and one-half times the diameter, the number of rivets shall be increased at least one per cent. for each additional 1/16 inch of grip. If the grip exceeds six times the diameter, the rivets shall be specially designed.

### Gage and Pitch of Rivets

412. A gage line is a line, straight or curved, through the centers of a row of rivets. A pitch line is a straight line through the center of a rivet and normal to the gage line.

The gage of rivets is the distance between adjacent parallel gage lines or between the back of an angle and the adjacent gage line. The pitch of rivets is the distance between adjacent pitch lines of rivets on the same or different gage lines.

The maximum pitch in the direction of stress for members composed of plates and shapes shall be seven times the diameter of the rivets.

At the ends of built compression members, the pitch in the direction of stress shall not exceed four times the diameter of the rivets for a distance one and one-half times the width of the member.

### Stitch Rivets

412a. Where two or more web plates are in contact, there shall be stitch rivets to make them act in unison. In compression members, the pitch of stitch rivets in the direction of stress shall not exceed 12 times the thickness of the thinnest outside plate connected, and the gage 24 times that thickness. In tension members, the maximum pitch or gage of stitch rivets shall be 24 times that thickness. In tension members composed of two angles in contact, the pitch of the stitch rivets shall not exceed 12 inches.

### Minimum Spacing of Rivets

412b. The minimum distance between centers of rivets shall be three times the diameter of the rivets.

### Edge Distance of Rivets

413. The distance from the center of a rivet to a sheared edge shall not be less than one and three-fourths times the diameter, nor to a rolled or planed edge less than one and one-half times the diameter, except in flanges of beams and channels, where the minimum distance may be one and one-fourth times the diameter.

The distance from the center of a rivet to the edge of a plate shall not exceed eight times the thickness of the plate.

### Sizes of Rivets in Angles

413a. The diameter of the rivets in angles whose size is determined by calculated stress shall not exceed one-fourth of the width of the leg in which they are driven. In angles whose size is not so determined, 1-inch rivets may be used in 3½-inch legs, ⅞-inch rivets in 3-inch legs, and ¾-inch rivets in 2½-inch legs.

### Compression Splices

414. Members subject to compression only, if faced for bearing, shall be spliced on four sides sufficiently to hold the abutting parts true to place. The splice shall be as near a panel point as practicable and shall be designed to transmit at least one fourth of the stress through the splice material. Members not faced for bearing shall be fully spliced.

### Extra Rivets

415. If splice plates are not in direct contact with the parts which they connect, there shall be rivets on each side of the joint in excess of the number required in the case of direct contact, to the extent of two extra lines for each intervening plate.

If rivets carrying stress pass through fillers, the fillers shall be extended beyond the connected member and the extension secured by enough additional rivets to carry one-half of the stress passing through the fillers.

### Stay Plates

416. On the open sides of compression members, the segments shall be connected by lacing bars and there shall be stay plates as near each end as practicable. There shall be stay plates at intermediate points where the lacing is interrupted. In main members the length of the end stay plates shall be not less than one and one-fourth times the distance between the lines of rivets connecting them to the outer flanges. The length of intermediate stay plates shall be not less than three-fourths of that distance and the thickness not less than one-fiftieth of that distance.

417. The segments of tension members composed of shapes shall be stayed together. The length of the stay plates shall be not less than two-thirds of the lengths specified for stay plates on compression members. They shall be connected to each segment by at least three rivets.

### Lacing

418. Lacing bars of compression members shall be so spaced that the slenderness ratio of the portion of the flange included between the lacing bar connections will be not more than 40 nor more than two-thirds of the slenderness ratio of the member.

419. In compression members, the shearing stress normal to the member in the plane of the lacing shall be that obtained by the following formula,

$$V = \frac{P}{100} \left( \frac{100}{\frac{l}{r} + 10} + \frac{\frac{l}{r}}{100} \right)$$

$V$  = normal shearing stress.

$P$  = allowable compressive axial load on member.

$l$  = length of member, in inches.

$r$  = radius of gyration of section about the axis perpendicular to plane of lacing, in inches.

To the shear so determined shall be added any shear due to the weight of the member or to other forces, and the lacing proportioned for the combined shear.

420. The shear shall be considered as divided equally among all parallel planes in which there are shear resisting elements, whether continuous plates or lacing. The section of the lacing bars shall be determined by the formula for axial compression in which  $l$  is taken as the distance along the bar between its connections to the main segments.

421. If the distance across the member between rivet lines in the flanges is more than 15 inches and a bar with a single rivet in the connection is used, the lacing shall be double and riveted at the intersections. In smaller members single lacing is preferable.

In large members with double lacing, there shall be transverse tie bars between connections to the segments.

The angle between the lacing bars and the axis of the member shall be approximately 45 degrees for double lacing and 60 degrees for single lacing.

422. Lacing bars may be shapes or flat bars. The minimum thickness of flat bars shall be one-fortieth of the distance along the bar between its connections, for single lacing, and one-sixtieth for double lacing, but not less than three-eighths inch.

The diameter of the rivets in lacing bars shall not exceed one-third of the width of the bar. There shall be at least two rivets in each end of lacing bars riveted to flanges more than 5 inches in width.

### Reinforcing Plates at Pin Holes

423. Where necessary for the required section or bearing area, the section at pin holes shall be increased on each segment by plates so arranged as to reduce the eccentricity of the segment to a minimum. One plate on each side shall be as wide as the outstanding flanges will allow. At least one full width plate on each segment shall extend to the far edge of the stay plate and the others not less than 6 inches beyond the near edge. These plates shall be connected by enough rivets to transmit the bearing pressure and so arranged as to distribute it uniformly over the full section.

### Forked Ends

424. Forked ends will be permitted only where unavoidable. There shall be enough pin plates on forked ends to make the section of each jaw equal to that of the member. The pin plates shall be long enough to develop the pin plate beyond the near edge of the stay plate, but not less than the length required by Article 423.

### Floor Beams

425. Floor beams preferably shall be square to the girders or trusses.

### End Connection Angles

426. The connection angles for stringers, floor beams, and beams in solid floor sections shall be not less than 4 inches in width and  $\frac{1}{2}$  inch in finished thickness.

### Proportioning Plate Girders

427. Plate girders and other members subject to bending that produces net tension on one face shall be proportioned by the moment-of-inertia method, using the net section of the compression side as well as of the tension side.

### Flange Section

428. The gross section of the compression flange of a plate girder or a rolled beam shall not be less than the gross section of the tension flange.

Flanges of plate girders preferably shall be made without cover plates or side plates unless angles of greater section than 6 inches  $\times$  6 inches  $\times$   $\frac{7}{8}$  inch would otherwise be required.

Cover plates shall be equal in thickness, or shall diminish in thickness from the flange angles outward. No plate shall be thicker than the flange angles. When cover plates are used, at least one plate on each flange shall extend the full length of the girder. Other flange plates shall extend far enough to allow two rows of rivets at each end of the plate, beyond the theoretical end, and there shall be enough rivets to develop the plate between its end and the theoretical end of the next plate outside.

In through bridges, there shall be end and corner cover plates.

### Flange Rivets

429. The flanges of plate girders shall be connected to the web with enough rivets to transmit to the flange section the horizontal shear at any point together with any load that is applied directly on the flange. Where the ties rest on the flange, one wheel load shall be assumed to be distributed over three feet.

### Flange Splices

430. Flange members that are spliced shall be covered by extra material equal in section to the member spliced. There shall be enough rivets on each side of the splice to transmit to the splice material the stress value of the part cut.

Flange angles shall be spliced with angles. No two members shall be spliced at the same cross-section.

### Web Splices

431. Splices in the webs of plate girders shall be designed for both the shear and the moment at the splice.

### Thickness of Web Plates

431a. The thickness of web plates shall be not less than 1/170 of the clear distance between the flanges.

### Stiffeners at Points of Bearing

432. Stiffener angles shall be placed at end bearings and at points of bearing of concentrated loads. The outstanding legs shall be proportioned for bearing and shall extend as nearly as practicable to the edges of the flange angles. Such stiffeners shall not be crimped. They shall be connected to the web by enough rivets to transmit the stress.

### Intermediate Stiffeners

433. If the depth of the web between the flanges or side plates of a plate girder exceeds 60 times its thickness, it shall be stiffened by pairs of angles riveted to the web. The spacing of the stiffeners, center to center, shall not exceed 72 inches nor shall the clear spacing be greater than that given by the formula:

$$d = \frac{255000t}{S} \sqrt[3]{\frac{St}{a}}$$

$d$  = clear distance between stiffeners, in inches.

$t$  = thickness of web, in inches.

$a$  = clear depth of web between flanges or side plates, in inches.

$S$  = unit shearing stress, gross section, in web at point considered.

The width of the outstanding leg of each angle shall be not more than 16 times its thickness and not less than two inches plus 1/30 of the depth of the girder.

### Bracing of Top Flanges of Through Girders

434. The top flanges of through plate girders shall be braced at the panel points by brackets with web plates. The brackets shall extend to the top flange of the main girder and be as wide as the clearance will allow. They shall be attached securely to a stiffener angle on the girder and to the top flange of the floor beam. On solid floor bridges the brackets shall be not more than twelve feet apart.

### Lateral Bracing

435. There shall be bottom lateral bracing in all spans except deck spans less than 50 feet long.

There shall be top lateral bracing in deck spans and in through spans that have enough head room.

### Portal and Sway Bracing

436. In through truss spans there shall be portal bracing, with knee braces, as deep as the clearance will allow. There shall be sway bracing at the intermediate panel points

if the trusses are high enough to allow a depth of 6 feet or more for such bracing. If they are not high enough to allow that depth, the top lateral struts shall be of the same depth as the chord, and there shall be knee braces as deep as the clearance will allow.

In deck truss spans there shall be sway bracing at the panel points. The top lateral forces shall be carried to the supports by means of a complete system of bracing in the planes of the top chords and the main end posts.

### **Rigid Bracing**

437. Lateral bracing shall be rigid and there shall be not less than three rivets in each end connection.

If the bracing is a double system and the members meet the requirements for both tension and compression members, both systems may be considered effective simultaneously.

### **Cross Frames**

438. In deck plate girder spans there shall be cross frames at the ends and at intervals not exceeding 18 feet. The end frames shall be proportioned for the centrifugal and lateral forces.

If there are two lines of stringers under each track in panels more than 20 feet in length, they shall be connected by cross frames.

### **Viaducts**

439. Viaducts shall consist of spans supported on bents. The bents preferably shall be composed of not more than two columns braced together. They shall be united in pairs by bracing to form towers except where single bents are necessary.

The columns preferably shall be made with a transverse batter of one horizontal to six vertical for single track viaducts, and one horizontal to eight vertical for double track viaducts.

The bracing of bents and towers shall consist of double systems of rigid diagonals with struts at caps and bases and at intermediate panel points. In double track towers there shall be bracing to transmit the longitudinal force to both sides.

The bottom struts shall be proportioned for either the calculated stresses or a stress in tension or compression equal to one-fourth of the dead load reaction on one pedestal, whichever is greater. The column bearings shall be designed to allow for the expansion and contraction of the tower bracing.

Anchor bolts for viaduct towers and similar structures shall be designed to engage a mass of masonry the weight of which is at least one and one-half times the uplift.

Where long spans are supported on short single bents, the bents shall be made with hinged ends or else the columns and anchorage shall be proportioned for the bending stresses produced by temperature changes and the elastic deformation of the span.

### **Eye-Bars**

440. The thickness of eye-bars shall be not less than one inch nor more than two inches. The section of the head through the center of the pin-hole shall exceed that of the body of the bar by at least 35 per cent. The form of the head shall be submitted to the Engineer for approval before the bars are made. The diameter of the pin shall be not less than eight-tenths of the width of the widest bar attached.

### **Eye-Bar Packing**

441. The eye-bars of a set shall be symmetrical about the central plane of the truss and as nearly parallel as practicable. The inclination of any bar to the plane of the

truss shall not exceed  $1/16$  inch to the foot. The bars shall be packed close, held against lateral movement, and so arranged that those in the same panel will not be in contact.

### Expansion

442. The design shall be such as to allow for the expansion and contraction of the span at the rate of one inch in 100 feet. In spans more than 300 feet long, allowance shall be made for the expansion in the floor.

### End Bearings

443. In spans more than 70 feet long, there shall be rollers or rockers at one end. Shorter spans shall be designed to slide on bearings with smooth surfaces.

Bearings and ends of spans shall be secured against lateral movement.

End bearings on masonry preferably shall be raised above the bridge seat by metal pedestals or bolsters.

### Rollers

444. Expansion rollers may be either cylindrical or segmental and shall be not less than 6 inches in diameter. They shall be coupled together with substantial side bars and geared to the upper and lower plates. The roller nest shall be so designed that the parts may be cleaned readily.

### Pedestals and Shoes

445. Pedestals and shoes preferably shall be made of cast steel. The difference in width between the top and the bottom bearing surfaces shall not exceed twice the vertical distance between them. For hinged bearings, this distance shall be measured from the center of the pin. In built pedestals and shoes, the web-plates and the angles connecting them to the base plate shall be not less than  $3/4$  inch thick. If the size of the pedestal permits, the webs shall be rigidly connected by diaphragms. The minimum thickness of the metal in cast steel pedestals shall be one inch. Pedestals and shoes shall be so designed that the load will be distributed uniformly over the entire bearing surface.

In spans more than 70 feet long there shall be hinged bearings at both ends.

### Inclined Bearings

446. For spans on an inclined grade and without hinged bearings, either the sole plates or the masonry plates shall be beveled so that the masonry surfaces may be made level.

### Anchor Bolts

447. Anchor bolts shall be not less than  $1\frac{1}{4}$  inches in diameter and long enough to extend 12 inches into the masonry. There shall be washers under the nuts. Anchor bolt holes in pedestals and sole plates shall be  $3/8$  inch larger in diameter than the bolts and at expansion points the holes in the sole plates shall be slotted.

### Camber

448. The camber of trusses shall be equal to the deflection produced by the dead load plus a load of 3000 pounds per foot of track. The camber of plate girders more than 90 feet in length shall be equal to the deflection produced by the dead load only.

### Screw Threads

449. Screw threads shall be U. S. Standard except that for pin ends of diameters greater than  $1\frac{3}{8}$  inches, the number of threads shall be six to an inch.

### Pins

450. In pins more than 9 inches in diameter, there shall be a hole not less than 2 inches in diameter bored longitudinally on the center line.

451. The turned bodies of pins shall be long enough to extend at the ends  $\frac{1}{4}$  inch beyond the outside faces of the parts connected. The pins shall be secured by chambered nuts or by solid nuts and washers. If the pins are bored, through rods with cap washers may be used. The screw ends shall be long enough to allow burring the threads.

452. Pin-connected members shall be secured in such a way as to limit lateral movement on the pin. Filler rings shall be made of metal not less than  $\frac{1}{2}$  inch thick.

### Name Plates

453. There shall be a name plate, showing in raised letters and figures the name of the manufacturer and the year of construction, bolted to the bridge near each end at a point convenient for inspection.

## SECTION 5—WORKMANSHIP

### General

501. The workmanship and finish shall be equal to the best general practice in modern bridge shops. Material at the shops shall be kept clean and protected from the weather as far as practicable.

### Straightening Material

502. Rolled material must be straight before being laid off or worked. Straightening shall be done by methods that will not injure the material. Sharp kinks and bends shall be cause for rejection.

### Finish

503. Shearing, chipping, and flame cutting shall be done neatly and accurately. Portions of the work exposed to view shall be neatly finished.

### Punching and Reaming

504. Holes may be punched full-size in material used for lateral, longitudinal, or sway bracing, lacing, stay plates, and diaphragms, if the material is not more than  $\frac{7}{8}$  inch thick. Holes in main material forming a part composed of not more than three thicknesses may be punched full-size if no thickness is more than  $\frac{5}{8}$  inch.

If there are more than three thicknesses or if any thickness is more than  $\frac{5}{8}$  inch, the holes in all of the thicknesses shall be punched-and-reamed, except that if any thickness is more than the nominal diameter of the rivets minus  $\frac{1}{8}$  inch, the holes in that thickness shall be drilled.

### Holes

505. Holes shall be punched full-size, punched-and-reamed, or drilled. The finished hole shall be  $\frac{1}{16}$  inch larger than the nominal diameter of the rivets.

For holes punched full-size, the diameter of the die shall not exceed that of the punch by more than  $\frac{3}{32}$  inch.

Holes punched-and-reamed shall be punched  $\frac{3}{16}$  inch smaller than the nominal diameter of the rivets and reamed to the finished size. Drilled holes shall be drilled to finished size while all of the thicknesses of metal are assembled; or else sub-drilled and reamed as required for punched-and-reamed holes.

Holes shall be cleancut, without torn or ragged edges. Holes that must be enlarged to admit the rivets shall be reamed. Drilling shall be done accurately. Poor matching of holes shall be cause for rejection.

Holes for turned bolts shall be reamed so that the bolt will make a tight fit.

Holes shall be cylindrical and perpendicular to the member.

### **Reaming and Drilling**

506. Reaming and drilling shall be done with twist drills. Drills used for reaming preferably shall be directed by mechanical means.

### **Reaming after Assembling**

507. Reaming shall be done after the pieces forming a built member are assembled and so firmly bolted together that the surfaces are in close contact. Burrs on the outside surfaces shall be removed. The pieces shall be taken apart before riveting, if necessary, and any shavings removed. If it is necessary to take the members apart for shipping or handling, the pieces reamed together shall be so marked that they may be reassembled in the same position. Reamed parts shall not be interchanged.

### **Shop Assembling**

511. The parts of riveted members shall be well pinned and firmly drawn together with bolts before riveting is begun. The drifting done during assembling shall be only such as to bring the parts into position and not to enlarge the holes or distort the metal.

### **Field Connections**

512. Solid floor sections and the floor beams and stringers of open floors shall be assembled in the shop with the girders or trusses, or in suitable frames. The connections shall be made to fit either by reaming the parts while so assembled or by reaming to metal templates.

513. Riveted trusses and the chords of pin-connected trusses shall be assembled to line and fit in the shop, either in whole or in part, and the holes for field connections drilled or reamed while the parts are so assembled; or else such holes shall be reamed to metal templates so placed as to secure the same result as assembling. Holes for other field connections, except those in lateral, longitudinal, and sway bracing, shall be reamed or drilled to a metal template.

### **Match-Marking**

514. Connecting parts assembled in the shop for the purpose of reaming or drilling holes in field connections shall be match-marked, and a diagram showing such marks furnished the Engineer.

### **Rivets**

515. The size of rivets called for on the plans shall be the size before heating.

516. Rivet heads shall be of approved shape and of the same size for each diameter of rivet. They shall be full, neatly made, concentric with the rivet holes, and in full contact with the surface of the member.

### **Riveting**

517. Rivets shall be heated uniformly to a light cherry red and driven while hot. They shall be free from slag, scale, and carbon deposit. When driven, they shall completely fill the holes. Loose, burned, or otherwise defective rivets shall be replaced. In removing rivets, care shall be taken not to injure the adjacent metal and, if necessary, they shall be drilled out. Caulking or recupping shall not be done.

518. Rivets shall be driven by direct-acting riveters where practicable. The pressure shall be continued after the upsetting has been completed.

519. When rivets are driven with a pneumatic riveting hammer, a pneumatic buckler shall be used where practicable.

### Field Rivets

520. Field rivets shall be furnished in excess of the nominal number required to the amount of 15 per cent., plus ten rivets, for each size and length.

521. Field rivets shall be free from fins on the under side of the head.

### Turned Bolts

522. Turned bolts used to transmit shear shall be  $\frac{1}{32}$  inch less in diameter than the hole and the threaded portion  $\frac{1}{16}$  inch less than the shank. The length of the shank shall be  $\frac{1}{16}$  inch greater than the grip. There shall be a washer not less than  $\frac{1}{4}$  inch thick under the nut.

### Planing Sheared Edges

523. Sheared edges of main material more than  $\frac{5}{8}$  inch thick shall be planed to a depth of  $\frac{1}{4}$  inch. Re-entrant cuts shall be filleted before cutting.

### Flame Cutting

523a. Flame cutting of main material shall not be done unless permitted by the Engineer.

### Lacing Bars

524. The ends of lacing bars shall be rounded unless otherwise required.

### Fit of Stiffeners

525. Stiffeners under the top flanges of deck plate girders and at all bearing points shall be milled or ground to bear against the flange angles. The fit of other stiffeners against the flange angles must be such as to exclude water after being painted. Fillers and splice plates shall be made to fit within  $\frac{1}{4}$  inch at each end.

### Web Plates

526. The edges of web plates of girders that have no cover plates shall not be more than  $\frac{1}{8}$  inch above or below the backs of the top flange angles. Web plates of girders that have cover plates may be  $\frac{1}{2}$  inch less in width than the distance back to back of flange angles.

527. In splices of web plates there shall be not more than  $\frac{3}{8}$  inch opening between the plates.

### Facing Floor Beams, Stringers, and Girders

528. Floor beams, stringers, and girders having end connection angles shall be made to exact length. If facing is necessary, the thickness of the end connection angles shall not be reduced more than  $\frac{1}{8}$  inch at any point.

The ends of the web plate shall be within  $\frac{1}{8}$  inch of the backs of the end connection angles.

### Finished Members

529. Finished members shall be true to line and free from twists, bends, and open joints.

### Abutting Joints

530. In joints and splices of compression members and girder flanges, and of tension members where so specified on the drawings, the abutting surfaces shall be faced and  
1038)

brought to an even bearing. Where the abutting surfaces are not faced, the opening shall not be more than  $\frac{1}{4}$  inch.

### Eye-Bars

531. Eye-bars shall be straight, true to size, and free from twists, folds in the neck or head, and other defects. The heads shall be made by upsetting, and rolling or forging. Welding shall not be done. The thickness of the head and neck shall not overrun more than:

$\frac{1}{16}$  inch for bars 8 inches or less in width.

$\frac{3}{8}$  inch for bars more than 8 inches and not more than 12 inches wide.

$\frac{3}{16}$  inch for bars more than 12 inches wide.

532. Both ends of eye-bars shall be bored at the same time. Bars that are to be placed side by side in the structure shall be bored so accurately that the pins may be passed through the holes at both ends at the same time without driving when the bars are placed together.

### Annealing

533. Steel that has been partially heated, except that to be used in minor parts, shall be annealed.

Eye-bars shall be annealed by heating uniformly to the proper temperature followed by slow and uniform cooling. Instruments shall be used to determine at all times the temperature of the bars.

A record of the annealing charges showing the bars in each charge and details of the treatment as to the temperature and time, shall be available to the Engineer.

### Boring Pin Holes

535. Pin holes shall be bored true to gage, smooth, straight, at right angles with the axis of the member, and parallel with each other, unless otherwise required. The tolerance in the length from outside to outside of pin holes of tension members, or from inside to inside of pin holes of compression members, shall be  $\frac{1}{32}$  inch for each 75 feet or fraction thereof. In built-up members the boring shall be done after the member has been riveted.

### Pin Clearances

537. The difference in diameter between the pin and the pin hole shall be  $\frac{1}{50}$  inch for pins up to 5 inches in diameter, and  $\frac{1}{32}$  inch for larger pins.

### Pins and Rollers

538. Pins and rollers shall be turned accurately to gage and shall be straight, smooth, and free from flaws.

### Screw Threads

539. Screw threads shall be made a close fit in the nut.

### Forging Pins

540. Pins more than 7 inches in diameter shall be forged and annealed.

### Fitting of Base and Cap Plates

541. The top and bottom surfaces of base and cap plates of columns and pedestals shall be planed, or else hot-straightened, and the parts of members in contact with them faced to fit. Connection angles for base plates and cap plates shall be riveted to compression members before the members are faced.

### **Surfaces of Bearing Plates and Pedestals**

542. Sole plates of plate girders shall be in full contact with the girder flanges. Sole plates and masonry plates shall be planed or straightened. In cast pedestals, bearing surfaces to be in contact with steel or masonry shall be planed.

### **Pilot Nuts**

543. Two pilot nuts and two driving nuts for each size of pin shall be furnished unless otherwise specified.

### **Shop Painting**

544. Unless otherwise specified, steel work shall be given one coat of approved paint after it has been accepted by the Inspector and before it is moved from the shop. Surfaces to be in contact shall be clean when assembled. They shall not be painted. Surfaces not to be in contact but inaccessible shall be painted before the parts are assembled.

Surfaces of metal to be painted shall be cleaned thoroughly, removing rust, mill scale, dirt, oil, grease, and other foreign substances. Oil and grease shall be removed with benzine or gasoline.

Paint shall not be applied on damp or frosted surfaces.

The paint shall be mixed thoroughly and the pigment kept in suspension until the paint is applied.

### **Machined Surfaces**

545. Machine finished surfaces of steel (except abutting joints and base plates) shall be coated with white lead and tallow applied as soon as the surfaces have been finished and accepted by the Inspector.

### **Facilities for Inspection**

546. The Contractor shall afford the Inspector, without charge, facilities for the inspection of materials and workmanship. The Inspector shall be allowed free access to the parts of the works used in the fabrication.

### **Material Orders and Shipping Statements**

547. The Contractor shall furnish to the Engineer as many copies of material orders and shipping statements as the Engineer may require. The weights of the individual members shall be shown on the statements.

### **Notice of Beginning Work**

548. The Contractor shall give the Engineer ample notice of the beginning of rolling in the mill and of work in the shop, in order that inspection may be provided. Material shall not be rolled nor work done in the shop before the Engineer has been so notified.

### **Inspector's Authority**

549. The Inspector shall have authority to reject materials or workmanship that do not meet the requirements of these specifications. In case of dispute, the Contractor may appeal to the Engineer, whose decision shall be final.

### **Rejection**

550. The acceptance by the Inspector of material or finished members shall not be a bar to their rejection later if found defective.

Rejected material and workmanship shall be replaced promptly or made good by the Contractor.

## SECTION 6—FULL-SIZE TESTS OF EYE-BARS

**Eye-Bars**

601. The acceptance of eye-bars shall depend on the results of full-size tests. The Contractor shall furnish, without charge, the testing machines, tools, and labor necessary to make the tests.

**Number of Full-Size Tests**

602. The number and size of the bars to be tested shall be stipulated by the Engineer before the mill order is placed. The number shall not exceed 5 per cent. of the whole number of bars ordered, with a minimum of two bars.

**Selection of Test Bars**

603. Test bars shall be of the same section and with pin holes of the same size as the bars ordered and of the same length if within the capacity of the testing machine. They shall be selected by the Inspector from the forged and annealed bars, except that those from bars too long for the testing machine shall be selected from the full-length bars after the heads on one end have been formed. They then shall be cut and the second head formed to make a bar of the greatest length that can be tested.

**Physical Properties**

604. The minimum requirements for full-size eye-bar tests shall be as follows:

|                                                    |              |
|----------------------------------------------------|--------------|
| Yield point, in pounds per square inch .....       | 33,000       |
| Ultimate strength, in pounds per square inch ..... | 60,000       |
| Elongation in 18 feet.....                         | 12 per cent. |

The measurement of the elongation shall be made in the part of the bar that includes the fracture.

The fracture shall be in the body of the bar. The appearance of the surface at the fracture shall be silky throughout, indicating a finely granular structure.

**Retests**

605. If a bar fails to meet the requirements of Article 604, two additional bars of the same size from the same mill heat shall be tested. The bars represented by the test may be reannealed before the additional bars are tested. If two of the three bars tested fail, the bars of that size and mill heat shall be rejected.

**Payment for Test Bars**

606. Bars tested full-size shall be paid for by the Company at the same rate as the bars accepted if they meet the requirements of the specifications. Bars that fail to meet the requirements and those rejected as a result of tests, shall not be paid for by the Company. The scrap from bars tested shall be the property of the Contractor.

## SECTION 7—WEIGHING AND SHIPPING

**Pay Weight**

701. The payment in pound-price contracts shall be based on the scale weight of the metal in the fabricated structure, including field rivets shipped, or, if permitted by the Engineer, payment may be based on computed weights. The weight of field paint and cement, boxes and barrels used for packing, and material used for staying or supporting members on cars, shall not be included.

Scale weight in excess of  $1\frac{1}{2}$  per cent. above the computed weight shall not be included in the weight paid for.

**Variance in Weight**

702. If the scale weight of any member is less than  $97\frac{1}{2}$  per cent. of the computed weight, it shall be cause for rejection.

**Computed Weight**

703. The weights of rolled shapes and of plates up to and including 36 inches in width shall be computed on the basis of their nominal weights and dimensions as shown on the approved shop drawings, deducting for copes, cuts, and open holes. For plates more than 36 inches in width, there shall be added to the nominal weight one-half the allowed percentage of overrun in weight given in Article 822.

The weight of the heads of shop driven rivets shall be included in the computed weight.

The weights of castings shall be computed from the dimensions shown on the approved shop drawings, with 10 per cent. added for fillets and overrun.

**Weight per Cubic Inch**

704. The weight of steel shall be assumed as 0.2833 pound per cubic inch.

The weight of cast iron shall be assumed as 0.2604 pound per cubic inch.

**Weighing**

705. The finished work shall be weighed in the presence of the Inspector if practicable. The Contractor shall furnish suitable scales and handle the material for weighing.

**Marking and Shipping**

706. Erection marks shall be painted on the members. The weight shall be marked on members weighing more than 10 tons.

Rivets and bolts shall be in separate packages according to length and diameter. Loose nuts and washers shall be in separate packages according to size. Pins, other small parts, and packages of rivets, bolts, nuts, and washers shall be shipped in boxes, crates, kegs, or barrels, none of which exceeds 300 pounds gross weight. On the outside of each container shall be marked plainly a list and description of the material therein.

**Loading Long Girders**

707. Long girders shall be so loaded and marked that they may be delivered at the bridge site in position for erection without turning. Instructions for such delivery shall be given to the receiving carrier.

**Shipment of Anchorage Material**

708. Anchor bolts, washers, and other anchorage or grillage materials to be built into the masonry shall be shipped in time therefor.

## **PART II—MATERIALS**

### **SECTION 8—STRUCTURAL AND RIVET STEEL**

**Process**

801. Structural and rivet steel shall be made by either or both of the following processes: open-hearth or electric-furnace.

## Chemical Composition

802. The steel shall conform to the following requirements as to chemical composition:

|                                                                | <u>Structural Steel</u> |      | <u>Rivet Steel</u> |       |
|----------------------------------------------------------------|-------------------------|------|--------------------|-------|
| Phosphorus, per cent.                                          |                         |      |                    |       |
| Acid .....                                                     | not over                | 0.06 | not over           | 0.06  |
| Basic .....                                                    | " "                     | 0.04 | " "                | 0.04  |
| Sulphur, per cent .....                                        | " "                     | 0.05 | " "                | 0.045 |
| Copper, when copper-bearing steel is specified, per cent. .... | not under               | 0.20 | not under          | 0.20  |

## Ladle Analyses

803. An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of carbon, manganese, phosphorus, and sulphur; also copper when copper-bearing steel is specified. This analysis shall be made from a test ingot taken during the pouring of the melt. The chemical composition thus determined shall be reported to the Engineer, and if it does not conform to the requirements of Article 802, the melt shall be rejected.

## Check Analyses

804. Analyses may be made by the Engineer from finished material representing each melt. If the phosphorus and sulphur content thus determined exceeds that specified in Article 802 by more than 25 per cent., the melt shall be rejected.

## Rolled Base Plates

804a. Rolled base plates over 2 inches in thickness, for bearing purposes, shall be of steel containing 0.20 to 0.35 per cent. carbon. The chemical composition shall conform to the requirements of Article 802. A discard shall be made from each ingot sufficient to secure sound plates. Physical tests will not be required.

## Physical Properties

805. The steel, other than the forms described in Articles 804a and 805a, shall conform to the following requirements as to physical properties, except as specified in Articles 806 and 807:

| <i>Properties Considered</i>                | <u>Structural Steel</u>        | <u>Rivet Steel</u>             |
|---------------------------------------------|--------------------------------|--------------------------------|
| Tensile strength, lb. per sq. in.....       | 60,000-72,000                  | 52,000-62,000                  |
| Yield point, minimum, lb. per sq. in.....   | 0.5 tens. str.                 | 0.5 tens. str.                 |
| but in no case less than .....              | 33,000                         | 28,000                         |
| Elongation in 8 in., minimum, per cent..... | <u>1,500,000</u><br>tens. str. | <u>1,500,000</u><br>tens. str. |
| Elongation in 2 in., minimum per cent.....  | 22                             | .....                          |

805a. Tension tests will not be required for flat rolled steel 3/16 in. and under in thickness, shapes less than 1 sq. in. in section, and bars, other than flats, less than 1/2 in. in thickness or diameter.

806. In order to meet the requirements of Article 604 for the physical properties of full-size annealed eye-bars, the manufacturer of the eye-bars shall determine the physical properties required for the specimen tests. The steel shall conform to the requirements of Articles 805, 807, and 810 as to physical properties other than tensile strength.

### Modifications in Elongation

807. For structural steel over  $\frac{3}{4}$  in. in thickness or diameter, or under  $\frac{5}{16}$  in. thick, deductions from the percentage of elongation in 8 in. specified in Article 805 shall be made as follows:

Over  $\frac{3}{4}$  in., deduct 0.25 per cent. for each  $\frac{1}{32}$  in. over  $\frac{3}{4}$  in., to a minimum elongation of 18 per cent.

Under  $\frac{5}{16}$  in., deduct 1.25 per cent. for each  $\frac{1}{32}$  in. under  $\frac{5}{16}$  in.

### Yield Point

808. The yield point shall be determined by the drop of the beam or the halt in the gage of the testing machine.

### Speed of Testing Machine

809. The cross-head speed of the testing machine shall be such that the beam can be kept balanced, but in no case shall the values given in the following table be exceeded:

| <u>Gage Length of Specimen</u> | <i>Maximum Cross-head Speed (inches per minute) in determining:</i> |                         |
|--------------------------------|---------------------------------------------------------------------|-------------------------|
|                                | <u>Yield Point</u>                                                  | <u>Tensile Strength</u> |
| 2 in. ....                     | 0.5                                                                 | 2.0                     |
| 8 in. ....                     | 2.0                                                                 | 6.0                     |

### Bend Tests

810. The test specimens for structural steel shall be bent cold through 180 degrees around a pin, the diameter of which is in the following ratio to the thickness of the specimen:

| <u>Thickness of Material</u>                 | <u>Ratio</u>   |
|----------------------------------------------|----------------|
| Up to $\frac{3}{4}$ in., inclusive.....      | $\frac{1}{2}$  |
| Over $\frac{3}{4}$ to 1 in., inclusive.....  | 1              |
| Over 1 to $1\frac{1}{2}$ in., inclusive..... | $1\frac{1}{2}$ |
| Over $1\frac{1}{2}$ to 2 in., inclusive..... | $2\frac{1}{2}$ |
| Over 2 in. ....                              | 3              |

If there is any cracking on the outside of the bent portion, the melt shall be rejected.

811. The test specimens for rivet bars shall be bent cold through 180 degrees flat. If there is any cracking on the outside of the bent portion, the melt shall be rejected.

### Test Specimens

812. Test specimens shall be prepared from the material in its rolled or forged condition except as specified in Article 813.

813. Test specimens for annealed material, except eye-bars, shall be prepared from the material as annealed for use, or from a short length of a full section similarly treated.

Tension and bend test specimens for rivet bars that have been cold drawn shall be normalized before testing.

814. Test specimens shall be so taken that the axis coincides with the direction of rolling and, except as specified in Articles 815 and 816, shall be of the full thickness or diameter of the material as rolled.

Test specimens for plates, shapes, and flats may be machined to the form and dimensions shown in Fig. 4, or with both edges parallel.

FIG. 4

815. Tension test specimens for material over  $1\frac{1}{2}$  inches in thickness or diameter, except pins and rollers, may be machined to a thickness or diameter of not less than  $\frac{3}{4}$  inch for a length of not less than 9 inches, or they may conform to the dimensions shown in Fig. 5.

FIG. 5

Bend test specimens for material over  $1\frac{1}{2}$  inches in thickness or diameter, except pins and rollers, may be machined to a thickness or diameter of not less than  $\frac{3}{4}$  inch or to a section 1 inch by  $\frac{1}{2}$  inch.

816. Tension test specimens for pins and rollers shall conform to the dimensions shown in Fig. 5, and bend test specimens shall be 1 inch by  $\frac{1}{2}$  inch in section.

Test specimens for pins and rollers shall be so taken that the axis is one inch from the surface.

817. The machined edges of rectangular bend test specimens may have the corners rounded to a radius of not over  $1/16$  inch.

### Number of Tests

818. Two tension and two bend tests shall be made from each melt, unless the finished material from the melt is less than 30 tons, when one tension and one bend test will be sufficient. If the material rolled from one melt varies  $\frac{3}{8}$  in. or more in thickness, one tension and one bend test shall be made from both the thickest and the thinnest material regardless of the weight represented.

819. If a test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

### Retests

820. A retest shall be allowed if the percentage of elongation of any specimen is less than that specified in Article 805 and if, in addition, any part of the fracture of a 2-inch specimen is more than  $\frac{3}{4}$  inch from the center of the gage length or of an 8-inch specimen is outside the middle third of the gage length as indicated by scribe marks made on the specimen before testing.

### Finish

821. The finished material shall be free from injurious defects. The finish shall be workmanlike.

### Permissible Variations in Weight and Thickness

822. The section or weight of any structural-size shape or of any universal mill plate up to and including 36 inches in width shall not differ more than 2.5 per cent. from that specified. The thickness and weight of rectangular sheared plates and of rectangular universal mill plates over 36 inches in width shall be governed by the following permissible variations:

- (a) When ordered to thickness, the thickness of each plate shall not vary more than 0.01 inch under that ordered. The overweight of each lot of plates in each shipment shall not exceed the amount given in Table II. The term "lot" as applied to Table II means all of the plates of each group width and group thickness.
- (b) Plates over 2 in. in thickness shall conform to the permissible variations over the ordered thickness given in Table III. The thickness of each plate shall not vary more than 0.01 in. under that ordered.

Steel is assumed to weigh 0.2833 lb. per cu. in.

### Permissible Variations in Diameter

823. The diameter of rivet bars shall not differ from the size ordered more than the amount given in the following table:

| <i>Diameter</i>                                      | <i>Difference in inches</i> |              |
|------------------------------------------------------|-----------------------------|--------------|
|                                                      | <i>Over</i>                 | <i>Under</i> |
| Up to and including $\frac{1}{2}$ inch.....          | 0.007                       | 0.007        |
| Over $\frac{1}{2}$ , up to and including 1 inch..... | 0.010                       | 0.010        |
| Over 1, up to and including 2 inches.....            | 1/32                        | 1/64         |

### Identification Marks

824. The name or brand of the manufacturer and the melt number shall be stamped or rolled legibly on the finished material, except that rivet bars, lacing bars, and other small sections shall be made into bundles and the bundles marked for identification. These identification marks shall be stamped legibly on one end of each pin and roller. The melt number shall be marked legibly, by stamping if practicable, on each test specimen.

### Inspection

825. The Inspector shall be allowed free access, while work on the contract of the Company is in progress, to the parts of the works used in the manufacture of the mate-

TABLE II.—PERMISSIBLE OVERWEIGHTS OF RECTANGULAR PLATES ORDERED TO THICKNESS

| Ordered Thickness,<br>Inches        | Permissible Excess in Average Weights per Square Foot of Plates for Widths Given, Expressed<br>in Percentages of Nominal Weights. |                           |                           |                           |                           |                            |                             |                             | Ordered Thickness,<br>Inches |

Tables II and III are identical with the tables of the same numbers in A. S. T. M. Standards, Serial Designation A 7-33.

rial ordered. The manufacturer shall, without charge, afford the Inspector facilities for making the inspection and furnish the test specimens required, and the testing machines, tools, and labor necessary to make the tests.

Inspections and tests (except check analyses) shall be made at the place of manufacture before shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

### **Rejection**

826. Unless otherwise agreed, any rejection based on check analyses shall be reported within five working days from the receipt of the samples.

Specimens representing material rejected as the result of check analyses, shall be preserved for two weeks from the date of the report. In case of dissatisfaction with the result, the manufacturer shall be allowed a rehearing within that time.

Material in which any injurious defect is found after its acceptance at the works will be rejected and the manufacturer so notified.

## **SECTION 9—STRUCTURAL SILICON STEEL**

### **Process**

901. Structural silicon steel shall be made by either or both of the following processes: open-hearth or electric-furnace.

### **Discard**

902. A discard shall be made from each ingot sufficient to secure freedom from injurious piping and undue segregation.

### **Chemical Composition**

903. The steel shall conform to the following requirements as to chemical composition:

|                        | <i>Ladle Analyses</i> |        | <i>Check Analyses</i> |         |
|------------------------|-----------------------|--------|-----------------------|---------|
| Carbon, per cent.....  | Not over              | 0.40   | Not over              | 0.44    |
| Phosphorus, per cent.  |                       |        |                       |         |
| Acid .....             | "                     | " 0.06 | "                     | " 0.075 |
| Basic .....            | "                     | " 0.04 | "                     | " 0.05  |
| Sulphur, per cent..... | "                     | " 0.05 | "                     | " 0.063 |
| Silicon, per cent..... | Not under             | 0.20   | Not under             | 0.18    |

### **Ladle Analyses**

904. An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of carbon, manganese, phosphorus, sulphur, and silicon. The analysis shall be made from a test ingot taken during the pouring of the melt. The chemical composition thus determined shall be reported to the Engineer, and if the percentages of carbon, phosphorus, sulphur and silicon do not conform to the requirements of Article 903 for ladle analyses, the melt shall be rejected.

### **Check Analyses**

905. Analyses may be made by the Engineer from finished material representing each melt. If the chemical composition thus determined does not conform to the requirements of Article 903 for check analyses, the melt shall be rejected.

## Physical Properties

906. The steel shall conform to the following requirements as to physical properties, except as specified in Article 907:

|                                          |                                       |
|------------------------------------------|---------------------------------------|
| Tensile strength, lb. per sq. in.....    | 80,000 to 95,000                      |
| Yield point, min., lb. per sq. in.....   | 45,000                                |
| Elongation in 8 in., min., per cent..... | $\frac{1,500,000}{\text{tens. str.}}$ |
| Elongation in 2 in., min., per cent..... | $\frac{1,600,000}{\text{tens. str.}}$ |
| Reduction of area, min., per cent.....   | 30                                    |

## Modification in Ductility

907. For structural silicon steel over  $\frac{3}{4}$  inch thick, deductions from the percentages of elongation and reduction of area specified in Article 906, shall be made as follows:

A deduction of 0.25 per cent, from the elongation in 8 inches for each  $\frac{1}{16}$  inch above  $\frac{3}{4}$  inch, to a minimum elongation of 14 per cent.

A deduction of 0.50 per cent. from the reduction of area for each  $\frac{1}{16}$  inch above  $\frac{3}{4}$  inch, to a minimum reduction of area of 24 per cent.

## Yield Point

908. The yield point shall be determined by the drop of the beam or the halt in the gage of the testing machine when operated at a cross-head speed not exceeding  $\frac{1}{2}$  in. per minute. The testing machine shall not be stopped to obtain the drop of the beam or the halt in the gage.

## Bend Tests

909. Test specimens shall be bent cold through 180 degrees around a pin, the diameter of which is in the following ratio to the thickness of the specimen:

| <u>Thickness of Material</u>            | <u>Ratio</u>   |
|-----------------------------------------|----------------|
| Up to $\frac{3}{4}$ in. inclusive.....  | 1              |
| Over $\frac{3}{4}$ to 1 in. wide .....  | $1\frac{1}{2}$ |
| Over 1 to $1\frac{1}{4}$ in. wide ..... | 2              |
| Over $1\frac{1}{4}$ .....               | $2\frac{1}{2}$ |

If there is any cracking on the outside of the bent portion, the melt shall be rejected.

## Drift Tests

909a. Punched rivet holes with their centers two diameters from a planed edge shall be enlarged by drifting until the diameter is increased 50 per cent. If there is any cracking of the metal the melt shall be rejected.

## Test Specimens

910. Test specimens shall be prepared from the material in its rolled or forged condition except as specified in Article 911.

911. Test specimens for annealed material shall be prepared from the material as annealed for use, or from a short length of a full section similarly treated.

912. Test specimens shall be so taken that the axis coincides with the direction of rolling and, except as specified in Article 913, shall be of the full thickness or diameter of the material as rolled.

Test specimens for plates, shapes, and flats may be machined to the form and dimensions shown in Fig. 4, Article 814, or with both edges parallel.

913. Tension test specimens for material over  $1\frac{1}{2}$  in. in thickness or diameter may be machined to a thickness or diameter of not less than  $\frac{3}{4}$  inch for a length of not less than 9 inches.

Bend test specimens for material over  $1\frac{1}{4}$  inches in thickness or diameter may be machined to a thickness or diameter of not less than  $\frac{3}{4}$  inch or to a section 1 inch by  $\frac{1}{2}$  inch.

914. The machined edges of rectangular bend test specimens may have the corners rounded to a radius of not over  $1/16$  inch.

### Number of Tests

915. Two tension tests and one bend test shall be made from each melt, except that if the material rolled from one melt varies  $\frac{3}{8}$  inch or more in thickness, one tension and one bend test shall be made from both the thickest and the thinnest material.

916. If a test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

### Retests

917. A retest shall be allowed if the percentage of elongation of any specimen is less than that specified in Article 906, and if, in addition, any part of the fracture is outside the middle third of the gage length as indicated by scribe marks made on the specimen before testing.

### Permissible Variations in Weight and Thickness

918. The section or weight of each piece of steel shall not differ more than 2.5 per cent. from that specified except in the case of sheared plates, which shall be governed by the requirements of Article 822 for rectangular sheared plates.

### Finish

919. The finished material shall be free from injurious defects. The finish shall be workmanlike.

### Identification Marks

920. The name or brand of the manufacturer and the melt number shall be stamped or rolled legibly on the finished material. The melt number shall be marked legibly, by stamping if practicable, on each test specimen.

### Inspection

921. The Inspector shall be allowed free access, while work on the contract of the Company is in progress, to the parts of the works used in the manufacture of the material ordered. The manufacturer shall, without charge, afford the Inspector facilities for making the inspection and furnish the test specimens required, and the testing machines, tools, and labor necessary to make the tests.

Inspections and tests (except check analyses) shall be made at the place of manufacture before shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

### Rejection

922. Unless otherwise agreed, any rejection based on check analyses shall be reported within five working days from the receipt of the samples.

Specimens representing material rejected as the result of check analyses, shall be preserved for two weeks from the date of the report. In case of dissatisfaction with the result, the manufacturer shall be allowed a rehearing within that time.

Material in which any injurious defect is found after its acceptance at the works will be rejected and the manufacturer so notified.

## SECTION 10—STRUCTURAL NICKEL STEEL

### Process

1001. Structural nickel steel shall be made by either or both of the following processes: open-hearth or electric-furnace.

### Discard

1002. A discard shall be made from each ingot intended for eye-bars sufficient to secure freedom from injurious piping and undue segregation.

### Chemical Composition

1003. The steel shall conform to the following requirements as to chemical composition:

|                           |           |      |
|---------------------------|-----------|------|
| Carbon, per cent .....    | Not over  | 0.45 |
| Manganese, per cent ..... | " "       | 0.70 |
| Phosphorus, per cent.     |           |      |
| Acid .....                | " "       | 0.05 |
| Basic .....               | " "       | 0.04 |
| Sulphur, per cent.....    | " "       | 0.05 |
| Nickel, per cent .....    | Not under | 3.25 |

### Ladle Analyses

1004. An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of carbon, manganese, phosphorus, sulphur, and nickel. This analysis shall be made from a test ingot taken during the pouring of the melt. The chemical composition thus determined shall be reported to the Engineer, and if it does not conform to the requirements of Article 1003, the melt shall be rejected.

### Check Analyses

1005. Analyses may be made by the Engineer from finished material representing each melt. If the chemical composition thus determined does not conform to the requirements of Article 1003, the melt shall be rejected.

### Physical Properties

1006. The steel shall conform to the following requirements as to physical properties, except as specified in Articles 1007 and 1008:

| <u>Properties Considered</u>             | <u>Plates, Shapes<br/>and Bars</u> | <u>Eye-bar Flats<br/>and Rollers,<br/>Unannealed</u> | <u>Eye-bar Flats<br/>and Pins,<br/>Annealed</u> |
|------------------------------------------|------------------------------------|------------------------------------------------------|-------------------------------------------------|
| Tensile strength, lb. per sq. in.....    | 85,000–100,000                     | 95,000–110,000                                       | 90,000–105,000                                  |
| Yield point, min., lb. per sq. in.....   | 50,000                             | 55,000                                               | 52,000                                          |
| Elongation in 8 in., min., per cent..... | <u>1,500,000</u><br>tens. str.     | <u>1,500,000</u><br>tens. str.                       | 20                                              |
| Elongation in 2 in., min., per cent..... | 18                                 | 16                                                   | 20                                              |
| Reduction of area, min., per cent.....   | 25                                 | 25                                                   | 35                                              |

Tests of annealed specimens of eye-bar flats shall be made for information only. The elongation of pins and rollers shall be measured in 2 inches.

## Test of Eye-Bars

1007. Full-size tests of annealed eye-bars shall conform to the following requirements as to physical properties:

|                                           |                   |
|-------------------------------------------|-------------------|
| Tensile strength, lb. per sq. in.....     | 85,000 to 100,000 |
| Yield point, min., lb. per sq. in.....    | 48,000            |
| Elongation in 18 ft., min., per cent..... | 10                |
| Reduction of area, min., per cent.....    | 30                |

## Modification in Elongation

1008. For plates, shapes, and unannealed bars over 1 in. in thickness, a deduction of 0.25 per cent. from the percentage of elongation in 8 in. specified in Article 1006, shall be made for each 1/32 in. in thickness above 1 in. to a minimum elongation of 14 per cent.

## Yield Point

1009. The yield point for test specimens shall be determined by the drop of the beam or the halt in the gage of the testing machine; for full-size eye-bars by the halt in the gage.

## Speed of Testing Machine

1010. The cross-head speed of the testing machine, for specimen tests, shall be such that the beam of the machine can be kept balanced, but in no case shall the values given in the following table be exceeded:

| <u>Gage Length of<br/>Specimen</u> | <i>Maximum Cross-head Speed (inches per minute)<br/>in determining:</i> |                         |
|------------------------------------|-------------------------------------------------------------------------|-------------------------|
|                                    | <u>Yield Point</u>                                                      | <u>Tensile Strength</u> |
| 2 in. ....                         | 0.5                                                                     | 2.0                     |
| 8 in. ....                         | 2.0                                                                     | 6.0                     |

## Character of Fracture

1011. The appearance at the surface of the fracture of broken tension test specimens shall be either silky or finely granular, of uniform color, and free from coarse crystals.

## Bend Tests

1012. Test specimens shall be bent cold through 180 degrees as follows:

- (a) For material  $\frac{3}{4}$  inch or less in thickness, around a pin the diameter of which is equal to the thickness of the specimen.
- (b) For material more than  $\frac{3}{4}$  inch in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen.

If there is any cracking on the outside of the bent portion, the melt shall be rejected.

## Drift Tests

1013. Punched rivet holes with their centers two diameters from a planed edge shall be enlarged by drifting until the diameter is increased 50 per cent. If there is any cracking of the metal the melt shall be rejected.

## Test Specimens

1014. Specimens shall be prepared for testing from the material in its rolled or forged condition except as specified in Article 1015.

1015. Test specimens for annealed material, except eye-bars, shall be prepared from the material as annealed for use, or from a short length of a full section similarly treated.

1016. Test specimens shall be so taken that the longitudinal axis coincides with the direction of rolling and, except as specified in Articles 1017 and 1018, shall be of the full thickness or diameter of the material as rolled.

Test specimens for plates, shapes, and flats may be machined to the form and dimensions shown in Fig. 4, Article 814, or with both edges parallel.

1017. Tension test specimens for material over  $1\frac{1}{2}$  inches in thickness or diameter, except pins and rollers, may be machined to a thickness or diameter of not less than  $\frac{3}{4}$  inch for a length of not less than 9 inches, or they may conform to the dimensions shown in Fig. 5, Article 815.

Bend test specimens for material over  $1\frac{1}{2}$  inches in thickness or diameter, except eye-bar flats, pins, and rollers, may be machined to a thickness or diameter of not less than  $\frac{3}{4}$  inch or to a section 1 inch by  $\frac{1}{2}$  inch.

1018. Tension test specimens for pins and rollers shall conform to the dimensions shown in Fig. 5, Article 815, and bend test specimens shall be 1 inch by  $\frac{1}{2}$  inch in section.

Test specimens for pins and rollers shall be so taken that the axis is one inch from the surface.

1019. The machined edges of rectangular bend test specimens may have the corners rounded to a radius of not over  $1/16$  inch.

### Number of Tests

1020. One tension and one bend test shall be made from each melt, except that if the material rolled from one melt varies  $\frac{3}{8}$  inch or more in thickness, both the thickest and the thinnest material shall be so tested.

1021. If a test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

### Retests

1022. A retest shall be allowed if the percentage of elongation of any specimen is less than that specified in Article 1006 and if, in addition, any part of the fracture of a 2-inch specimen is more than  $\frac{3}{4}$  inch from the center of the gage length or, of an 8-inch specimen is outside the middle third of the gage length as indicated by scribe marks made on the specimen before testing.

### Finish

1023. The finished material shall be free from injurious defects. The finish shall be workmanlike.

### Permissible Variations in Weight and Thickness

1024. The permissible variation in weight of structural nickel steel plates shall be the same as provided in Article 822 for structural steel plates.

### Identification Marks

1025. The name or brand of the manufacturer and the melt number shall be stamped or rolled legibly on the finished material, except that rivet bars, lacing bars, and other small sections shall be made into bundles and the bundles marked for identification. These identification marks shall be stamped legibly on one end of each pin and roller. The melt number shall be marked legibly, by stamping if practicable, on each test specimen.

### Inspection

1026. The Inspector shall be allowed free access, while work on the contract of the Company is in progress, to the parts of the works used in the manufacture of the mate-

rial ordered. The manufacturer shall, without charge, afford the Inspector facilities for making the inspection and furnish the test specimens required, and the testing machines, tools, and labor necessary to make the tests.

Inspections and tests (except check analyses) shall be made at the place of manufacture before shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

### Rejection

1027. Unless otherwise agreed, any rejection based on check analyses shall be reported within five working days from the receipt of the samples.

Specimens representing material rejected as the result of check analyses, shall be preserved for two weeks from the date of the report. In case of dissatisfaction with the result, the manufacturer shall be allowed a rehearing within that time.

Material in which any injurious defect is found after its acceptance at the works will be rejected and the manufacturer so notified.

## SECTION 11—STEEL FORGINGS

### Process

1101. Steel for forgings shall be made by either or both of the following processes: open-hearth or electric-furnace.

### Discard

1102. A discard shall be made from each ingot sufficient to secure freedom from injurious piping and undue segregation.

### Prolongation for Tests

1103. Unless otherwise specified, not less than 20 per cent. of the forgings shall be provided with prolongations for test purposes or, at the manufacturer's option and expense, a forging may be selected.

### Annealing

1104. Forgings shall be annealed. The procedure in annealing shall be as follows:

Allow the objects, immediately after forging, to cool to a temperature below the critical range under suitable conditions to prevent injury by too rapid cooling; then reheat uniformly to the proper temperature to refine the grain (a group thus reheated being known as an annealing charge) and allow to cool uniformly.

### Chemical Composition

1105. The steel shall conform to the following requirements as to chemical composition:

|                            |               |
|----------------------------|---------------|
| Manganese, per cent. ....  | 0.40-0.80     |
| Phosphorus, per cent. .... |               |
| Acid .....                 | Not over 0.05 |
| Basic .....                | Not over 0.05 |
| Sulphur, per cent. ....    | Not over 0.05 |

### Ladle Analyses

1106. An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of carbon, manganese, phosphorus, and sulphur. This analysis shall be made from a test ingot taken during the pouring of the melt. The chemical composition thus determined shall be reported to the Engineer, and if it does not conform to the requirements of Article 1105, the melt shall be rejected.

## Check Analyses

1107. An analysis may be made by the Engineer from a forging representing each melt. The chemical composition thus determined shall conform to the requirements of Article 1105. Drillings for analysis may be taken from the forgings or from a full-size prolongation thereof, at any point midway between the center and the surface of solid forgings, and at any point midway between the inner and the outer surfaces of the wall of bored forgings; or turnings may be taken from a test specimen.

## Physical Properties

1108. The forgings shall conform to the following requirements as to physical properties:

|                                                |                                                    |
|------------------------------------------------|----------------------------------------------------|
| Tensile Strength, minimum, lb. per sq. in..... | 60,000                                             |
| Yield point, minimum, lb. per sq. in.....      | 0.5 tens. str.                                     |
| but not less than.....                         | 33,000                                             |
| Elongation in 2 in., minimum, per cent.:       |                                                    |
| Not over 12 in. diam.....                      | $\frac{1,700,000}{\text{tens. str.}}$ not under 25 |
| Over 12 in. to 20 in. diam., incl.....         | $\frac{1,600,000}{\text{tens. str.}}$ not under 24 |
| Reduction of area, min., per cent.:            |                                                    |
| Not over 12 in. diam.....                      | $\frac{2,700,000}{\text{tens. str.}}$ not under 38 |
| Over 12 in. to 20 in. diam., incl.....         | $\frac{2,520,000}{\text{tens. str.}}$ not under 36 |

The classification of the forgings as to size shall be determined by the specified diameter or thickness which governs the size of the prolongation from which the test specimen is taken.

## Yield Point

1108a. The yield point shall be determined by the drop of the beam or the halt in the gage of the testing machine. The speed of the machine shall conform to the requirements of Article 809.

Tests of forgings shall be made only after the final treatment.

## Tension Test Specimens

1109. Tension test specimens shall be taken from a full-size prolongation of the forging. For forgings with large ends or collars the prolongation may be of the same cross-section as that of the forging back of the large end or collar. Specimens may be taken from the forging itself with a hollow drill, if approved by the Engineer.

The axis of the specimen may be located at any point midway between the center and the surface of solid forgings, and at any point midway between the inner and the outer surfaces of the wall of bored forgings, and shall be parallel to the direction in which the metal of the forging is most drawn out.

The specimens shall conform to the dimensions shown in Fig. 5, Article 815.

## Number of Tests

1110. Tests shall be made as follows:

One tension test shall be made from each annealing charge. If more than one melt is represented in an annealing charge one tension test shall be made from each melt.

If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

### Retests

1111. A retest shall be allowed if the percentage of elongation of any specimen is less than that specified in Article 1108 and if, in addition, any part of the fracture is more than  $\frac{3}{4}$  inch from the center of the gage length, as indicated by scribe marks made on the specimen before testing.

If the results of the physical tests of any test lot of forgings do not conform to the requirements specified, the manufacturer may re-anneal such lot one or more times and retests shall be made as specified in Article 1110.

### Finish

1112. The forgings shall be free from injurious defects. The finish shall be workmanlike.

### Identification Marks

1113. Identification marks shall be stamped legibly on each forging and on each test specimen.

### Inspection

1114. The Inspector shall be allowed free access, while work on the contract of the Company is in progress, to the parts of the works used in the manufacture of the material ordered. The manufacturer shall, without charge, afford the Inspector facilities for making the inspection and furnish the test specimens required, and the testing machines, tools, and labor necessary to make the tests.

Inspections and tests (except check analyses) shall be made at the place of manufacture before shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

### Rejection

1115. Unless otherwise agreed, any rejection based on check analyses shall be reported within five working days from the receipt of the samples.

Specimens representing material rejected as the result of check analyses, shall be preserved for two weeks from the date of the report. In case of dissatisfaction with the result, the manufacturer shall be allowed a rehearing within that time.

Material in which any injurious defect is found after its acceptance at the works will be rejected and the manufacturer so notified.

## SECTION 12—CAST STEEL

### Process

1201. Cast steel shall be made by one or more of the following processes: Open-hearth, electric-furnace, converter, or crucible.

### Annealing

1202. Castings shall be annealed. The procedure in annealing shall be as follows:

Allow the castings to cool, after pouring, to a temperature below the critical range, then reheat to the proper temperature and for the required time, to refine the grain, and allow to cool slowly in the furnace until the pyrometer shows that the furnace temperature has fallen to 500° Fahr. The furnace temperature shall be controlled effectively with pyrometers.

## Chemical and Physical Properties

1203. Test specimens of cast steel shall conform to the following requirements as to chemical composition and physical properties:

|                                                |              |
|------------------------------------------------|--------------|
| Phosphorus, maximum, per cent.....             | 0.05         |
| Manganese, per cent.....                       | 0.50 to 1.00 |
| Silicon, per cent.....                         | 0.20 to 0.75 |
| Sulphur, maximum, per cent.....                | 0.06         |
| Tensile strength, minimum, lb. per sq. in..... | 70,000       |
| Yield point, minimum, lb. per sq. in.....      | 38,000       |
| Elongation in 2 inches, minimum, per cent..... | 24           |
| Reduction of area, minimum, per cent.....      | 36           |

## Ladle Analyses

1204. An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of carbon, manganese, silicon, phosphorus, and sulphur. This analysis shall be made from drillings taken at least  $\frac{1}{4}$  inch beneath the surface of a test ingot obtained during the pouring of the melt. The chemical composition thus determined shall be reported to the Engineer and if it does not conform to the requirements of Article 1203, the melt shall be rejected.

## Check Analyses

1205. Check analyses may be made by the Engineer from a broken tension test specimen or from a casting representing each melt. The chemical composition thus determined shall conform to the requirements of Article 1203. Drillings for analysis shall be taken not less than  $\frac{1}{4}$  inch beneath the surface.

## Yield Point

1206. The yield point shall be determined by the drop of the beam or the halt in the gage of the testing machine at a cross-head speed not exceeding  $\frac{1}{8}$  in. per minute. The tensile strength shall be determined at a cross-head speed not exceeding  $1\frac{1}{2}$  in. per minute.

## Test Specimens

1208. Tension test specimens shall be taken from test bars cast attached to the castings where practicable. If, in the judgment of the manufacturer, the design of the castings is such that test bars attached directly to the castings might affect the castings or the test specimens injuriously, the test bars shall be cast attached to special blocks. Test bars from which tension test specimens are to be taken shall remain attached to the castings or blocks through annealing and until presented for inspection. Test bars shall be provided in sufficient numbers to furnish the tests required in Article 1211.

1209. Tension test specimens shall conform to the dimensions shown in Fig. 5, Article 815.

## Number of Tests

1211. One tension test shall be made from each melt in each annealing charge and, when specified, from each casting weighing 500 pounds or more.

1212. If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen from the same lot substituted.

## Retests

1213. A retest shall be allowed if the percentage of elongation of any specimen is less than that specified in Article 1203 and if, in addition, any part of the fracture is more

than  $\frac{3}{4}$  inch from the center of the gage length, as indicated by scribe marks made on the specimen before testing.

1214. If the results of the physical tests of any lot do not conform to the requirements, the manufacturer may re-anneal such lot not more than twice and retests shall be made as specified in Article 1211.

### Workmanship and Finish at Foundry

1215. The castings shall conform substantially to the drawings and shall be made in a workmanlike manner. The castings shall be free from injurious defects.

### Identification Marks

1216. The name or brand of the manufacturer and the melt number shall be stamped legibly on the finished castings. The melt number shall be marked legibly, by stamping if practicable, on each test specimen.

### Inspection

1217. The Inspector shall be allowed free access, while work on the contract of the Company is in progress, to the parts of the works used in the manufacture of the material ordered. The manufacturer shall, without charge, afford the Inspector facilities for making the inspection and furnish the test specimens required, and the testing machines, tools, and labor necessary to make the tests.

Inspections and tests (except check analyses) shall be made at the place of manufacture before shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

### Rejection

1218. Unless otherwise agreed, any rejection based on check analyses shall be reported within five working days from the receipt of the samples.

Specimens representing material rejected as the result of check analyses shall be preserved for two weeks from the date of the report. In case of dissatisfaction with the result, the manufacturer shall be allowed a rehearing within that time.

Material in which any injurious defect is found after its acceptance at the works will be rejected and the manufacturer so notified.

## SECTION 13—CAST IRON

### Process

1301. Cast iron shall be gray iron made by the cupola process.

### Finish

1302. Castings shall be true to pattern and free from excessive shrinkage. They shall be free from cracks, cold shuts, blow holes, and other flaws.

### Chemical Composition

1303. The sulphur content of cast iron shall not exceed:

|                           |                |
|---------------------------|----------------|
| For light castings .....  | 0.10 per cent. |
| For medium castings ..... | 0.10 per cent. |
| For heavy castings .....  | 0.12 per cent. |

Drillings taken from the fractured ends of the transverse test bars shall be used for the sulphur determinations. One determination shall be made from each of the two sets of test bars representing a melt.

## Classification

1304. Castings shall be classified as light, medium, and heavy.

- (a) Light castings are those with any section less than  $\frac{1}{2}$  inch thick.
- (b) Heavy castings are those with no section less than two inches thick.
- (c) Medium castings are those not included in either of the classes (a) or (b).

## Test Bars

1305. Transverse tests shall be made on the "Arbitration Test Bar" of the American Society for Testing Materials, Serial Designation A-124-29.

Two sets of two bars each shall be made from each melt, one set from the first iron poured and the other set from the last iron poured. If the melt exceeds 20 tons, an additional set of two bars shall be cast from each additional 20 tons or fraction thereof. Each set of two bars shall be cast in a single mold.

## Transverse Tests

1306. A transverse test of each bar shall be made. The bar shall be placed on supports spaced 18 inches apart and a load applied at the center.

The application of the load shall be at a rate that will produce a central deflection of 0.10 inch in from 20 to 40 seconds.

One bar of each set shall conform to the following minimum requirements, otherwise the melt shall be rejected:

|                                  | <i>Class of Casting</i> |               |              |
|----------------------------------|-------------------------|---------------|--------------|
|                                  | <i>Light</i>            | <i>Medium</i> | <i>Heavy</i> |
| Load at center, pounds .....     | 1,500                   | 1,750         | 2,000        |
| Deflection at center, inch ..... | 0.20                    | 0.20          | 0.20         |

## Inspection

1307. The Inspector shall be allowed free access, while work on the contract of the Company is in progress, to the parts of the works used in the manufacture of the material ordered. The manufacturer shall, without charge, afford the Inspector facilities for making the inspection and furnish the test specimens required, and the testing machines, tools, and labor necessary to make the tests.

Inspections and tests (except check analyses) shall be made at the place of manufacture before shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

## PART III—ALLOY STEELS

### FOREWORD

In issuing specifications for using alloy steels in railway bridges, the Committee deems it desirable to present in a Foreword thereto certain information, not appropriate as specification clauses but worthy of consideration when the use of an alloy steel is contemplated.

1. Nickel and silicon steels both have been used in important railway and highway bridges and have proved satisfactory. Other alloy steels have been used successfully.

2. Silicon steel can be obtained from practically all structural and plate mills, even in moderate tonnages if not ordered in too great a variety of sections. Nickel steel can be had by special arrangements with the mill and in larger tonnages; other alloys only by negotiation with the mills.

3. It is customary to use carbon steel rivets in fabricating alloy steels, the rivet values being based on the carbon rivet. In rare instances alloy steel rivets have been used with alloy steels. Studies are now going forward in the American Society for Testing Materials to develop specifications for rivet steels of strength suitable for economical use with alloy steels.

4. The modulus of elasticity is the same for the alloy steels as for carbon steel.

5. Short spans can be constructed most economically of carbon steel.

6. As span lengths increase and the influence of dead load becomes preponderant, a span of equal cost as between carbon steel and part alloy steel will be reached, but of two spans of equal cost in place, the heavier one (carbon steel) is the better purchase, for reasons of rigidity and thickness of material (resistance to corrosion).

7. With increasing length of span, the economy in use of alloy steel will become pronounced and the features of rigidity and resistance to corrosion will be amply protected in an alloy steel design. For such spans, and unless there is extreme need for reducing the dead load, the floor systems should be of carbon steel.

8. Nickel and silicon steels are excellent bridge steels, but it must be remembered that in every high-strength steel, whether high-carbon or alloy, some desirable property must be encroached upon to secure the added strength. While such steels have ample plastic action between yield point and ultimate strength, it is not as great as for carbon steel. While they have excellent ductility and bending properties, those properties are not quite so good as in carbon steel. Therefore, when such steels are used some effort should be made to compensate in the design and details for these differences. For that reason, the allowable unit stresses in these specifications are a somewhat smaller fraction of the specified yield point than those for carbon steel and slightly greater edge distances are desirable.

9. In considering other alloy steels as they are made available, tests should be made to develop the effect of rivet holes and riveting, before determining the allowable unit stresses. No steel should be considered satisfactory for bridge construction if its yield point exceeds 70 per cent. of the ultimate strength.

### SECTION 14—ALLOY STEELS

#### GENERAL

The term "Alloy Steel" means structural silicon steel or structural nickel steel.

The foregoing specifications shall apply to alloy steel parts of bridges except as provided otherwise herein.

## UNIT STRESSES

## Unit Stresses

1401. The allowable unit stresses to be used in proportioning the parts of a bridge shall be as follows:

|                                                                                                                                               | <i>Pounds per Square Inch</i>   |                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|---------------------------------|
|                                                                                                                                               | <i>Silicon Steel</i>            | <i>Nickel Steel</i>             |
| Axial tension, net section .....                                                                                                              | 24,000                          | 27,000                          |
| Stress in extreme fibers of rolled shapes, girders, and built sections, subject to bending, net section .....                                 | 24,000                          | 27,000                          |
| Axial compression, gross section, for values of $\frac{l}{r}$ not greater than 130: (see note)                                                |                                 |                                 |
| For riveted ends .....                                                                                                                        | $20,000 - 0.46 \frac{l^2}{r^2}$ | $22,500 - 0.57 \frac{l^2}{r^2}$ |
| For pin ends .....                                                                                                                            | $20,000 - 0.61 \frac{l^2}{r^2}$ | $22,500 - 0.76 \frac{l^2}{r^2}$ |
| NOTE.—For values of $\frac{l}{r}$ greater than 130 and for columns of known eccentricity, see Appendix A.                                     |                                 |                                 |
| Compression in extreme fibers of rolled shapes, girders, and built sections, subject to bending, for values of $\frac{l}{b}$ not greater than |                                 |                                 |
| 40, gross section .....                                                                                                                       | $24,000 - 6.67 \frac{l^2}{b^2}$ | $27,000 - 7.50 \frac{l^2}{b^2}$ |
| Stress in extreme fibers of pins .....                                                                                                        | 36,000                          | 40,000                          |
| Shear in plate girder webs, gross section ....                                                                                                | 14,000                          | 16,000                          |
| Shear in pins .....                                                                                                                           | 18,000                          | 20,000                          |
| Bearing on pins, outstanding legs of stiffener angles, and other steel parts in contact...                                                    | 36,000                          | 40,000                          |
| Bearing on rocker pins .....                                                                                                                  | 12,000                          | 13,000                          |

*Pounds per Linear Inch*

|                                               |      |      |
|-----------------------------------------------|------|------|
| Bearing on expansion rollers and rockers .... | 800d | 900d |
|-----------------------------------------------|------|------|

*d* = diameter of roller or rocker, in inches.

## Thickness of Material

1402. Metal, except for fillers, shall be not less than  $\frac{3}{8}$  inch thick. Silicon steel plates shall be not more than  $1\frac{1}{8}$  inches thick and nickel steel plates not more than 1 inch.

In compression members consisting of segments connected by cover plates or lacing, or segments connected by webs, the thickness of the webs of the segments shall be not less than  $\frac{1}{28}$  of the unsupported distance between the nearest rivet lines. The thickness of the cover plates or webs connecting the segments shall be not less than  $\frac{1}{36}$  of the unsupported distance between the nearest lines of their connecting rivets or the roots of their rolled flanges.

The thickness of the webs of plate girders shall be not less than  $\frac{1}{145}$  for silicon steel and  $\frac{1}{140}$  for nickel steel, of the clear distance between flange angles or side plates.

1402a. If the depth of the web between flanges or side plates of a plate girder exceeds 50 times its thickness, it shall be stiffened by pairs of angles riveted to the web in accordance with the requirements of Article 433.

### Sizes of Rivets

1403. The diameter of rivets in main members preferably shall be not less than 1 inch.

### Lacing

1404. In compression members, the shearing stress normal to the member in the plane of the lacing shall be that obtained by the following formula:

$$V = \frac{P}{100} \left( \frac{100}{\frac{l}{r} + 10} + \frac{l}{70} \right)$$

$V$  = normal shearing stress.

$P$  = allowable compressive axial load on member.

$l$  = length of member, in inches.

$r$  = radius of gyration of section about the axis perpendicular to plane of lacing, in inches.

To the shear so determined shall be added any shear due to the weight of the member or other forces, and the lacing proportioned for the combined shear.

### Rivets

1406. Silicon steel and nickel steel shall not be used for rivets. Rivets preferably shall be made of the rivet steel specified in Section 8. Other steels may be used for rivets and bolts if specified by the Engineer.

### Alloy and Structural Steels Combined

1407. In case the deformation of alloy steel elements of members or spans induces stresses in other elements exceeding the allowable stresses for structural steel, such other elements also shall be made of alloy steel. Otherwise, bracing and secondary truss members generally shall be made of structural steel. Lacing, stay plates, diaphragms, stiffening angles, and other detail material except gussets and splice plates shall be made of structural steel. For alloy steel elements, the workmanship shall be that specified for alloy steel.

### Secondary Stresses

1408. The design and details shall be such that secondary stresses will be as small as practicable. In trusses, secondary stresses due to truss distortion need not be considered in any member, the width of which, measured parallel to the plane of the truss, is less than one-tenth of its length. If the secondary stress exceeds 5,600 pounds per square inch for tension members and 4,200 for compression members, then the excess over 5,600 pounds per square inch for tension members, and 4,200 for compression members shall be treated as a primary stress.

**WORKMANSHIP****Holes**

1409. Alloy steels shall be either drilled or sub-punched and reamed. Silicon steel more than  $\frac{3}{4}$  inch thick and nickel steel more than  $\frac{5}{8}$  inch thick shall be drilled. The holes may be drilled  $\frac{1}{16}$  inch larger than the nominal diameter of the rivet or sub-drilled and reamed to that size. Material of less thickness may be either drilled as specified above, or else punched  $\frac{3}{16}$  inch smaller than the nominal diameter of the rivet and reamed to the finished size.

**Planing Sheared Edges**

1410. Sheared edges of alloy steel shall be planed to a depth of  $\frac{1}{4}$  inch.

## Appendix A

## COLUMN FORMULAS

The parabolic formulas for axial compression given in Articles 301 and 1401 fit the values obtained by the secant formula so closely that they may be used without substantial error for slenderness ratios within the limits shown.

The corresponding secant formulas are:

$$\text{For riveted ends. } p = \frac{\frac{y}{f}}{1 + 0.25 \text{ Sec.} \frac{0.75 l}{2r} \sqrt{\frac{fp}{E}}}$$

$$\text{For pin ends. } p = \frac{\frac{y}{f}}{1 + 0.25 \text{ Sec.} \frac{0.875 l}{2r} \sqrt{\frac{fp}{E}}}$$

The coefficient 0.25 in the denominator is the eccentric ratio,  $\frac{ec}{r^2}$ . It provides for the ordinary amount of crookedness and end eccentricity.

For columns centrally loaded, and having a slenderness ratio beyond the limit fixed for the parabolic formulas, one of the secant formulas above should be used.

For columns with known eccentricity of loading, the following formulas should be used for all slenderness ratios.

$$\text{For riveted ends. } p = \frac{\frac{y}{f}}{1 + \left( \frac{ec}{r^2} + .001 \frac{l}{r} \right) \text{ Sec.} \frac{0.75 l}{2r} \sqrt{\frac{fp}{E}}}$$

$$\text{For pin ends. } p = \frac{\frac{y}{f}}{1 + \left( \frac{ec}{r^2} + .001 \frac{l}{r} \right) \text{ Sec.} \frac{0.875 l}{2r} \sqrt{\frac{fp}{E}}}$$

$p$  = allowable compressive unit stress.

$l$  = length of member, in inches.

$r$  = least radius of gyration of member, in inches.

$c$  = distance from neutral axis to extreme fibre, in inches.

$e$  = known eccentricity of applied load, in inches.

$E$  = modulus of elasticity = 29,400,000.

$y$  = yield point in tension:

33,000 for structural steel.

45,000 for silicon steel.

50,000 for nickel steel.

$f$  = factor of safety based on yield point:

1.76 for structural steel.

1.80 for silicon steel.

1.78 for nickel steel.

## REPORT OF COMMITTEE XXVI—STANDARDIZATION

J. C. IRWIN, *Chairman*;

*Committee.*

### *To the American Railway Engineering Association:*

Your Committee respectfully presents herewith report covering the following assignments:

1. Encourage the use of A.R.E.A. recommended practices and consider subjects for recommendation to the Board of Direction for sponsoring as projects for National Standardization.

2. Maintain contact with Standardization bodies and keep the Association informed on important matters developed by such contact.

On the first assignment, important progress has been made during the year through contacts with the staff of the Federal Coordinator of Transportation, and specifically with the Section of Purchases, R. L. Lockwood, Director. These contacts began soon after the appointment of the Federal Coordinator and the creation of his organization.

The assurances, early received, that the Coordinator and his staff recognized the value of A.R.E.A. Recommended Practices and the experience and skill of the men responsible for them and proposed to aid in the extension of their use rather than to endeavor to create new ones, were welcomed by this Committee as the most far-reaching support the Association could have in the encouragement of the use of its Recommended Practices.

Mr. Lockwood's first effort was to find out what items that involve the greatest expenditure had been accepted as standards or were in shape for early submission as standards in the railway field. The most conspicuous items were the rail sections, the 131-lb. section having been adopted in the March, 1933, Convention, and the 112-lb. section having been adopted by letter-ballot in the summer of 1933. These sections, adopted as recommended practice, were submitted to the A.R.A. for endorsement. Action on these sections raised the question of the possibility of securing uniformity in joint bars, tie plates, and other track material to go with them. Progress on these items will be reported by the respective standing committees.

The chief function of this Committee has been to furnish information as to the status and to arrange for contacts which would promote an understanding of the situation with a view to advancing new subjects toward standardization beyond the adoption by the A.R.E.A. as recommended practice.

In view of this progressing situation, it was considered most effective to have a meeting of this Committee in Chicago in the fall and invite Mr. Lockwood to outline the policies of the Coordinator, and also to invite President Wiltsee and the other members of the Board of Direction and representatives of other Divisions of the A.R.A. to attend, thus avoiding duplication of effort, promoting understanding and securing co-operation between the Engineering Division and other Divisions of the A.R.A. In order

to make this meeting complete, President Wiltsee, as Chairman of the General Committee of the Engineering Division, called a meeting of that Committee for the same day and arranged for a joint session of that Committee and Committee XXVI—Standardization. This meeting was held October 6th, 1933, at the Palmer House, Chicago.

The joint session was attended by 56 men. President Wiltsee presided, outlined the new aspects of standardization and presented R. L. Lockwood, Director, Section of Purchases, Federal Coordinator of Transportation.

Mr. Lockwood explained how the organization of the Coordinator was set up under the General Enabling Act, the appointment of three Regional Directors and the work of the various sections, and, specifically, of his activities as Director of the Section of Purchases. He emphasized the need for greater simplification through the reduction of sizes and varieties of products and the coordination of standardizing bodies. He stated that it is not the policy of the Coordinator to set up an organization to create standards and that they preferred to put the seal of approval on an accepted fact, and would rely on the expert knowledge and experience represented by A.R.E.A. committees. He spoke of the situation on standards for rail, joint bars, other track material and lumber. He stated that the Coordinator's first press release had to do with materials purchased by the railroads whether purchased directly as commodities or as material furnished by contractors.

The meeting of Committee XXVI—Standardization, which followed this joint meeting, also was attended by Mr. Lockwood and his assistants, George A. Cooper and C. W. Brown, by the President and members of the Board of Direction, and by representatives of other Divisions of the A.R.A. At this meeting, the status of subjects for which National Standardization is considered desirable, was discussed, each member of the Committee, reporting as Chairman of a standing committee, on the status of such subjects under the jurisdiction of his Committee, general discussion following. The situation in regard to subjects being specifically advanced toward National Standardization is described under other sections of this report.

This Committee again emphasizes the fact that benefits of simplification through reduction of the number of types and sizes of materials and the standardization of the remaining types and sizes, can be secured only by setting aside objections due to small personal preferences and joining in with what the majority approves as recommended practices, these, in cases where wide interests are involved and where the economies warrant, to be advanced beyond the immediate railway field, as American Standards, for the use of all industries concerned.

This Committee also again requests members who find real objections to A.R.E.A. Recommended Practices, the use of which involves other interests as well as their own, to notify the Chairman of the A.R.E.A. Committee having jurisdiction over the portion of the Manual concerned, clearly stating the reasons for their objections so that the matter may be duly considered in connection with "Revision of Manual".

## SUBJECTS RECOMMENDED FOR NATIONAL STANDARDIZATION

The status of subjects reported by the Committee, under this heading, last year is as follows:

### Specifications for Creosote for Wood Preservation

Committee XVII—Wood Preservation, in its report this year, will submit to the Association for approval, revisions of A.R.E.A. specifications resulting from its joint work with the American Wood Preservers' Association and the American Society for

Testing Materials, which, if adopted, will practically establish uniform specifications for Creosote and for Creosote Coal-Tar. These specifications, if endorsed by the A.R.A. and sponsored by these associations as projects of the A.S.A., will be in a position for advancement as American Standards through procedure of the A.S.A.

### Specifications for Trolley Wire and Messenger Wire

Projects under this heading are developing through the American Society for Testing Materials, the American Transit Association and the Electrical Standards Committee of the A.S.A. The specifications for both copper and bronze trolley wire, already approved by the A.S.T.M. and the Electrical Section—A.R.A., are being handled under regular procedure of the A.S.A. and are progressing toward final adoption as American Standards. There appears to be no occasion for any action by this Association for their advancement.

### Wire and Sheet Metal Gages

This has been accepted as a project of the A.S.A. and is listed as B 32 P. This Committee reported the status last year and has made inquiries during the year. It appears that, for the lack of continuous support of its present sponsors, the project is making no progress. It has been suggested that the A.R.A. and possibly another Association take over the sponsorship and revive the work. This Committee has in progress inquiries as to the exact status and history of the project and what would be involved in carrying it through. The American Society of Mechanical Engineers and the Society of Automotive Engineers have sponsored the inauguration of the project but apparently they desire some other group to assume actual leadership.

At the meeting of this Committee held in Chicago, October 6th, 1933, W. M. Vandersluis, Chairman, Committee XVIII—Electricity, and J. E. Saunders, Chairman of the Signal Section, agreed that something should be done to develop comprehensive up to date wire tables. Other industries, notably, informally, representatives of the International Harvester Company of Canada, Ltd., have referred to the need for a uniform designation of wire sizes, and have made suggestions for a decimal system of numbering. Both the Signal Section and Division I—Operating, T.&T. Section, have representatives of record on the A.S.A. Sectional Committee on this project.

This Committee will continue to collect the necessary information to present to our Board of Direction with recommendations for action to be taken.

### Grading Rules and Dimensions of Lumber

This subject was presented in the meeting of this Committee in New York, May 20th, 1932, as one deserving study for National Standardization. The report of this Committee last year (Bulletin 351), included a statement in regard to the organizations working on lumber Standards and the procedure by which "American Lumber Standards" are issued by the Division of Simplified Practice, National Bureau of Standards. Record is made of the acceptances of these "Standards".

The current lumber standards of this character cover only softwoods (conifers). These are as follows:

"Simplified Practice Recommendation R16-29," issued in 1929, covering softwoods in general, with appendices on moldings and red cedar shingles.

"Supplement to Simplified Practice Recommendation R16-29", issued in 1933, further covering moldings and shingles.

The A.R.E.A. is recorded as an acceptor of both of these lumber standards. The former are largely incorporated in A.R.E.A. Manual beginning with "Grading Rules and Classification of Timber and Lumber for Railway Uses", on page 472. However, there appear to be difficulties in the application of these rules and classifications to the purchasers specifications and this situation is now under investigation. It seems probable that Consumer representation of broader scope than is had in the present processes, especially by increased representation from large consumer industries such as the railways, would promote more general understanding and would produce results more readily available for the purchaser.

This subject being brought under discussion at the meeting of this Committee in Chicago, October 6th, views that the present situation is unsatisfactory and requires clarification were expressed by H. Austill, Chairman, Committee VII—Wooden Bridges and

Trestles, W. T. Dorrance, member and former Chairman, Committee VI—Buildings, and Dr. Hermann von Schrenk, Consulting Timber Engineer, member Committee XVII—Wood Preservation and Director A.R.E.A. There were no objectors to this view. As a result of this discussion it was unanimously voted that this Committee recommend to the Board of Direction, A.R.E.A., that this subject be advanced as a project for the American Standards Association. It is being prepared with that recommendation in view. In this connection, the status of the present Simplified Practice Recommendations and their acceptance by the trade and consumers, and their use in the Lumber Code Authority issued under Executive Order are recognized. For the future, the work may lead to greater adaptation to the use of the purchaser and a more extensive participation by consumer interests, in new projects.

Additional subjects suggested by members of this Committee, at its meeting October 6th, for consideration for National Standardization are:

1. Galvanized Culvert Pipe (Geo. S. Fanning, Committee I—Roadway). This subject is being further developed by Committee I and is not yet ready for action by this Committee.
2. Track Scales (J. R. W. Ambrose, Vice-Chairman and M. J. J. Harrison, Committee XIV—Yards and Terminals). Discussion developed the fact that certain phases of this subject appear to be ready for recommendation for advancement and, at the meeting of Committee XIV, held October 9th and 10th, 1933 (subsequent to the meeting of this Committee), the following action was taken.

"It was voted to recommend, on behalf of the Yards and Terminals Committee, the specifications for Two and Four-Section Track Scales for Standardization by the American Standards Association".

This action of the Yards and Terminals Committee will be submitted to the full membership of this Committee with a view to recommendations to the Board of Direction. It refers to specifications in the Manual as follows:

Pages 1008 to 1026—Specifications for the Manufacture and Installation of Four-Section Railway Track Scales. (For Knife-Edge Scales only, not Including Overhead Suspension Scales). These specifications have been promulgated by the National Bureau of Standards as its Circular No. 83.

Pages 1050 to 1067—Specifications for the Manufacture and Installation of Two-Section Knife-Edge Railway Track Scales. These specifications have been promulgated by the National Bureau of Standards as its Circular No. 333.

The history of these projects has been submitted by Mr. Harrison.

3. Tank Hoop Lugs (R. C. Bardwell, Committee XIII—Water Service and Sanitation).

Mr. Bardwell called attention to difficulty in securing lugs as adopted by A.R.E.A. (Manual pages 940, 941). This difficulty apparently is due to the influence of the use of lugs, not conforming to A.R.E.A. recommended practice, by interests other than the railways. The subject will be investigated further to see whether the desired results should be obtained merely by demanding A.R.E.A. requirements or by endeavoring to bring about national standards conforming to them.

This Committee directs attention to the "Electrical Section Reports," Bulletin 359, page 42, Committee VII—Standardization of Apparatus and Materials, Sidney Withington, Chairman, with special reference to work under way as projects of the American Standards Association.

## STATUS OF A.R.A. RECOMMENDED STANDARDS FOR RAILROAD HIGHWAY GRADE CROSSING PROTECTION

This report of the Standardization Committee affords the medium for information to this Association of the progress in establishing uniform methods of protection for highways crossing railways at grade. Frank Ringer, former Director, Chairman of the

Joint Committee on Grade Crossing Protection, A.R.A., furnishes the following statement from his Committee.

"The Joint Committee on Grade Crossing Protection has continued to cooperate with the Railroad and Highway Commissions of the several states, upon request of the latter, and has furnished information that would be of service in determining their policy with respect to highway grade crossing protection.

"During the past year Utah and Missouri have, by Commission Order, adopted standards for grade crossing protection substantially in accord with American Railway Association recommended practice. Several states, among which are Connecticut, Massachusetts and Pennsylvania have approved installations of signals that conform to A.R.A. standards, and others are giving consideration to their use.

"The National Association of Railroad and Utilities Commissioners at their 1932 annual convention approved a committee report which included an endorsement of standards and practices as outlined in Bulletin No. 1. An invitation to attend the 1933 convention has been extended to the membership of the Joint Committee.

"The National Conference on Street and Highway Safety and the American Association of State Highway Officials over a year ago appointed a joint committee to recommend standards for highway signs and markings. This committee, upon which the Joint Committee on Grade Crossing Protection was represented, has recently presented a report which embodies a recommendation that A.R.A. standards be used.

"It is believed the railroads in general are showing an increased trend towards the use of uniform protection at grade crossings. Progress towards complete standardization must of a necessity come through a definite policy on the part of all carriers concerned. Such a policy, insofar as the various signs and signals are concerned, is set forth in our Bulletin No. 1. A gradual realization of this purpose is indicated."

American Railway Association,  
Joint Committee on Grade Crossing Protection.  
Washington, D. C.  
October 11, 1933.

#### AMERICAN STANDARDS ASSOCIATION (A.S.A.)

##### A.R.A. Representation in A.S.A.

###### Members of the Board of Directors

L. A. Downs (Elected as A.R.A. Representative)

J. C. Irwin (Ex-Officio, as Chairman, Standards Council)

###### Members of the Standards Council

Representative, Div. I —Operating; W. Rogers (term expires December 31, 1934)

" Div. IV—Engineering; J. C. Irwin (" " " 31, 1936)

" Div. V —Mechanical; W. I. Cantley  
(term expires December 31, 1935)

Alternates J. R. W. Ambrose  
E. K. Post  
J. S. Hagan  
J. E. Saunders  
L. C. Thomson

##### Relations between A.S.A. and National Bureau of Standards

The U.S. Department of Commerce, of which the Bureau of Standards is a part, is one of the Member Bodies of the A.S.A. Dr. Lyman J. Briggs, Director, National Bureau of Standards, is a Director of the A.S.A. and the Bureau has three Representatives and three Alternates on the Standards Council, A.S.A. Other U.S. Departments having membership in the A.S.A. and Representatives and Alternates on the Standards

Council are the Departments of Agriculture, Interior, Labor, Navy, War, the Government Printing Office and the Panama Canal. The Government, therefore, is participating very fully in the work of the A.S.A.

As stated in previous reports of this Committee, particularly in its report of November, 1931, Vol. 33, the Bureau of Standards has done very extensive work on simplification and standardization by bringing together the various interests involved in any industrial line and publishing the results of conferences as Simplified Practice Recommendations.

Early in the summer of 1933, Secretary of Commerce Daniel C. Roper, notified the President of American Standards Association, Howard Coonley, that the Bureau of Standards was discontinuing most of the work which it had been carrying on in the field of simplification, commercial standards, safety codes and building codes for the reason that he considered that these functions should be in the hands of industry and consumer groups and that as a result of conferences between Secretary Roper and Mr. Coonley the A.S.A. would be relied on to carry out the essentials of this work with the full co-operation of the Bureau of Standards. It was understood that the transfer of such activities would be made gradually. This arrangement permits of large savings in the Bureau of Standards with much smaller increases in the budget of the A.S.A. as it is organized to handle such work, with some changes. The responsibility was accepted by the Board of the A.S.A. and special committees of the Board of Directors and of the Standards Council were appointed to arrange for the financing and organization for the enlarged scope of the work.

A Conference was held in Washington October 19, 1933, at which all interested parties were invited to express their views on the handling of standardization. Assistant Secretary of Commerce John Dickinson presided. At this Conference Secretary Roper expressed his opinion that "whatever industry can satisfactorily do for itself should no longer be done at the expense of the taxpayer", and that with this view, and the need for economy in government, it was felt that the time had come to invite the American Standards Association to help carry the burden of commercial standardization activity which the government had been carrying. He also cited the A.S.A. as a quasi-governmental activity, because of the membership of seven government departments in A.S.A.

As a result of these preliminary arrangements, "Commercial Standards Monthly", the periodical of the Bureau of Standards, was merged with "Industrial Standardization", the periodical of the A.S.A., beginning with the issue of July, 1933, the merged paper carrying the title "Industrial Standardization and Commercial Standards Monthly". Attention is directed to the issue of July, 1933, with a cover statement by Dr. L. J. Briggs and report and correspondence between Secretary Roper and President Coonley in regard to the transfer of activities, and also to the issue of November, 1933, giving reports of their addresses before the Conference on Standardization held in Washington, October 19th, 1933.

Subsequent developments have led to modifications in the general plan of organization for standardization but with the same objective. A detailed plan for handling the work for the present is being worked out between the A.S.A. and the Bureau.

"Industrial Standardization and Commercial Standards Monthly" of October, 1933, contains valuable articles on Building and Plumbing Codes as follows:

"Building Codes" by George N. Thompson, formerly Chief of the Building Code Section of the National Bureau of Standards.

"The Plumbing Code Situation in the United States" by William C. Groeniger, Chairman, Sectional Committee on Standardization of Plumbing Equipment, American Society of Sanitary Engineering; Consulting Sanitary Engineer, Columbus, Ohio.

"The National Board of Fire Underwriters' Proposed Uniform Building Code" by Clinton T. Bissell, Associate Consulting Engineer, National Board of Fire Underwriters.

"Building Code Developments on the Pacific Coast" by David H. Merrill, Managing Secretary-Treasurer, Pacific Coast Building Officials' Conference, and

"A Uniform Building Code for the Municipalities of New England" by Edward W. Roemer, President, New England Building Officials' Conference; Building Commissioner, City of Boston.

### **Inch-Millimeter Conversion Tables for Industrial Use**

As a result of the adoption of the value 25.4 as the American Standard inch-millimeter ratio for industrial use as reported last year by this Committee, Vol. 33, page 314, conversion tables have been prepared which, together with descriptive matter, are published in a ten-page pamphlet with the title "American Standard Practice for Inch-Millimeter Conversion for Industrial Use". This may be secured at slight expense, varying with the number of copies ordered, from the American Standards Association, 29 West 39th Street, New York, N. Y.

### **General**

This report on the activities of the A.S.A. is supplemented by appendices as follows:

Appendix A—Standards Approved by the American Standards Association, Period September 1, 1932 to September 1, 1933.

Appendix B—American Standards Association Technical Projects on which the Railway Associations are now Cooperating.

### **CANADIAN ENGINEERING STANDARDS ASSOCIATION (C.E.S.A.)**

The following memorandum in regard to C.E.S.A. activities in 1933 up to September 30, is furnished by B. Stuart McKenzie, Secretary.

### **Civil Engineering and Construction**

Work has been confined to an investigation into the situation on building brick sizes. A special panel of the Committee on Building Materials has been gathering information through a questionnaire, and it is hoped shortly to make a definite recommendation for a standard size of building brick for use in Canada, and if this is adopted, to proceed with the standardization of other types of building materials.

### **Mechanical Engineering**

One standard has been issued during the year covering Binder Head Screws used in the electrical trade. After considerable investigation and discussion, agreement was reached on one standard design and six different sizes, which it is believed will effect a most useful simplification in connection with this particular project.

The draft Safety Code for Passenger and Freight Elevators has been prepared and sent out to the committee for comments, and it is hoped shortly to have a meeting to discuss revisions to the first draft.

Preparations are being made to consider standards for Wood Screws and Small Rivets.

The standard for Machine, Carriage and Plow Bolts has been held up waiting for information on certain changes which have been taking place in the trade, but it is hoped that this may possibly be issued before the end of the year. Information is being included in the specification to cover heavy bolts and nuts such as are used in railway practice, but the standard does not include track bolts.

## Electrical Work

A rather radical change in the electrical situation in Canada took place at the beginning of the year, when the Underwriters' Laboratories at Chicago practically withdrew from the field in Canada, and approval of electrical apparatus is done almost entirely by the Hydro-Electric Power Commission of Ontario in Toronto. Tests will now be made on specifications prepared by the Canadian Engineering Standards Association, and a label service has been inaugurated. Specifications covering Electric Signs and Electrical Equipment for Oil-burning Apparatus, also a special pamphlet covering Definitions and General Requirements in connection with all approval specifications, have been issued, and specifications for Electric Floor Surfacing and Cleaning Machines and Portable Electric Displays and Incandescent Lamp Signs are being printed. Specifications for Electric Clocks and Electric Fixtures will shortly be issued. Other specifications which have been prepared and are now being discussed cover Enclosed Switches, Service Entrance and Branch Circuit-breakers, Capacitors (Electrical Condensers), Fractional Horsepower Motors, Electric Portable Lighting Devices, Transformers for Luminous-tube Signs and Oil-burner Ignition Equipment, Industrial Control Equipment, Heating Pads, Insulated Conductors for Power-operated Radio Devices, Cable for Luminous-tube Signs and Oil-burner Ignition Equipment, Outlet Boxes, Soldering Lugs, Motor-operated Blowers and Stokers, Cord Sets and Gasoline Measuring and Discharge Devices.

The Third edition of Part I of the Canadian Electrical Code, covering wiring rules, is now being considered.

Committees are working on revisions to the specification for A.C. Watthour Meters, also a new specification for Demand Meters. Consideration is being given to drafts of new specifications for Power Transformers and for Insulating Oils, but it has not been possible to do much work on these during the year. New standards covering Enamelled Magnet Wire, Oil Circuit-breakers, and Insulated Power Cable are being prepared.

The Association has been somewhat handicapped during the year by a falling off of subscriptions from industry, but it has still been possible to carry on fairly satisfactorily and it is hoped that next year will bring a welcomed change.

The Association is now lodged in the National Research Building on Sussex Street, Ottawa, quarters having been provided by the National Research Council of Canada.

Ottawa, September 30, 1933.

Respectfully submitted,

THE COMMITTEE ON STANDARDIZATION,

J. C. IRWIN, *Chairman*.

#### Electrical Standards Committee—Sidney Withington

Sidney Withington is also a member of the U. S. Nat. Committee of the International Electrotechnical Commission—not as an A.R.A. Representative.

## DISCUSSIONS

## DISCUSSION ON UNIFORM GENERAL CONTRACT FORMS

(For Report, see pp. 309-332)

Mr. F. L. Nicholson (Norfolk Southern):—The report of Committee XX will be found in Bulletin 360, page 309.

On the first subject, Revision of Manual, the Committee has no report to make at this time.

On the second subject, Form of Agreement for the Purchase of Electrical Energy in Large Volume (such as required for traction purposes), this subject was assigned to Committee XX at the conclusion of the 1928 convention, and a Form of Agreement was prepared and submitted to Committee XVIII—Electricity. A progress report was made at the 1929 convention.

Shortly after that convention, the Electrical Section of the American Railway Association appointed Committee XVII to collaborate with Committee XX, and since that date there has been the closest possible collaboration in the preparation of this form.

In order that you may know something about the class of help that this Committee has had in the preparation of this form, I will simply remark that the Electrical Engineers of the Delaware, Lackawanna and Western, Illinois Central, New York Central, Atlantic Coast Line, the Baltimore and Ohio, the Pennsylvania Railroad, the New York, New Haven and Hartford, Reading, the Key System, Public Service Company of Northern Illinois, and the Niagara Junction Railway, collaborated with us. They were on Committee XVII of the Electrical Section.

So many differences of opinion arose in the Committee, and so many suggestions were received from prominent members of the National Electric Light Association, now the Edison Electric Institute, that the Committee submitted practically a new draft of agreement for the 1932 convention.

In passing I will say that it is almost impossible to get a trade or an industrial organization as such to endorse a Form of Agreement proposed by this organization. They will collaborate with us; their members will agree on the terms and conditions, but as to getting it, as an organization, to endorse it, is another matter. They feel that such endorsement ties their hands; they cannot enter into agreements with individual railroads if they have agreed to our forms.

In the preparation of the form, the Committee has given most careful consideration to the suggestions submitted by the various interested parties and has freely consulted published works of the American Electric Railway Engineering Association and the Association of Railway Electrical Engineers and will present to you the result of these years of painstaking labor, with the hope that the provisions in the form may meet with your approval for printing in the Manual as recommended practice.

I will ask Mr. W. G. Nusz, Chairman of the Sub-Committee, to present the report.

Mr. W. G. Nusz (Illinois Central):—A joint meeting of the Sub-Committee of Committee XX and the Sub-Committee of Committee XVII of the Electrical Section held this year considered all the comments and suggestions received by your Committee and a draft of the completed Form of Agreement is shown on pages 311 to 319 inclusive. For the purpose of discussion, we will consider the Agreement section by section.

I move the adoption of the Agreement as shown in Bulletin 360, pages 311 to 319 inclusive.

The President:—The question before you is the adoption of the recommendation of this Committee on the Agreement. Inasmuch as that is rather a lengthy Agreement, I

think the Chairman should offer each section by title to the convention and pause a few moments, allowing anybody to offer amendments or discussion.

Mr. W. G. Nusz:—The preamble is on page 311 and the top of page 312.

Article I, Term of Agreement.

Article II, Obligations as to Supply and Purchase.

Article III, Character of Service.

Article IV, Character of Load.

Article V, Points of Delivery.

Article VI, Rates and Payments.

Section 1. Primary and Secondary Charges.

Section 2. Determination of Demand.

Section 3. Right of Railway Company to Examine Records.

Section 4. Payments, Time when Due.

Article VII, Metering.

Section 1. Location and Ownership of Meters.

Section 2. Type of meters and right of railway to be represented at reading and testing of them.

Section 3. Testing and Adjustment of Meters.

Article VIII, Interruption, Default and Termination.

Section 1. Reduction in Primary Charge.

Section 2. Reduction in Secondary Charge.

Section 3. Termination by Railway Company for Poor Service.

Section 4. Termination by Railway Company due to Increase in Rates by the Power Company.

Section 5. Termination by Power Company for Non-Payment of Bills.

Section 6. Termination by Power Company for Interference to its Service to other Customers.

Article IX, Reduction in Rates.

Article X, Arbitration.

Article XI, General.

Section 1. Power Company's Right of Access to Railway Company's Property.

Section 2. Repair and Renewal of Apparatus.

Section 3. Indemnity Clauses.

Section 4. Waivers.

Section 5. Assignments.

The President:—The question before you is on the adoption of the motion to approve this Agreement for printing in the Manual. Is there any further discussion? Are you ready for the question? All those in favor will signify by saying "aye"; contrary. It is carried and so ordered.

Chairman F. L. Nicholson:—The next subject is Form of Conveyance of Title Granting the Right to Construct and Maintain Buildings over Railway Property. Mr. R. P. Eubank is Chairman of the Sub-Committee. The draft is submitted to you as information, and it is hoped that those interested in this subject will carefully review and give the benefit of their views to the Committee.

The President:—The report will be received as information unless there is objection thereto. It is so received.

Chairman F. L. Nicholson:—The next is Form of Agreement for Pipe Line Crossings under Railway Tracks—Appendix D; and Form of Agreement for Use of Railway Property by Pipe Lines Paralleling Railway, with Special Reference to Pipe Lines Carrying High Pressure Inflammable Oils or Gas.

When the Committee began preparation of these forms, it came to the conclusion that one form could and should be prepared to cover both assignments, and the form now presented has been prepared in collaboration with Committee I—Roadway and Committee XIII—Water Service and Sanitation.

I will ask Mr. Miller, Chairman of the Sub-Committee, to present the report.

Mr. A. A. Miller (Missouri Pacific):—Under Appendix D on page 325 of Bulletin 360 will be found the Form of Agreement for Pipe Line Crossings under Railway Tracks and for the Use of Railway Property by Pipe Lines Generally Paralleling the Railway, and it is there indicated that this Committee is submitting the form for your adoption and inclusion in the Manual.

Just recently information has come to this Committee that makes it desirable and advisable that work on this particular form be continued, and this report at this time we suggest be accepted as information.

The President:—The report will be so received unless there is objection to such action, and the subject will be continued.

Chairman F. L. Nicholson:—The next subject is Form of Agreement with Public Authorities for Highway Grade Crossing Elimination or Separation.

This Form of Agreement as prepared and submitted covers both over and under-pass grade separation. It is complete. But following the practice of the Committee to give ample opportunity for discussion and suggestions, it is submitted as a progress report with the hope that the members will favor the Committee with such suggestions as they care to make for its betterment, that the Committee may present at the next convention, for adoption, a form that will be most useful to you.

The President:—Is there objection to receiving this as a progress report? Is there any discussion on the subject? The report will be so received.

Chairman F. L. Nicholson:—That completes our report.

The President:—The Committee is relieved with the thanks of the Association for their excellent report (Applause).

## DISCUSSION ON YARDS AND TERMINALS

(For Report, see pp. 419-472)

Mr. M. J. J. Harrison (Pennsylvania):—The report of the Yards and Terminals Committee appears in Bulletin 361 commencing on page 419.

At this time your Committee recommends the revision of two sections of the Manual and the withdrawal of a third section thereof, and submits as information reports covering Grain Elevator Storage Yards and Plant Tracks, Hump Yards, Scales Used in Railway Service, Expediting of Freight Car Movements through Yards, and a Bibliography.

On the subject of Coordination of Facilities at Rail-and-Water Terminals, your Committee reports active work under way but not advanced sufficiently for the preparation of a report.

At this time your Committee wishes to acknowledge receipt of letters commenting on its present report. Such letters have been received from a gratifyingly large number of members of the Association, and your Committee wishes to thank these members for their interest. Their several comments will have the careful consideration of this Committee.

The first assignment is Revision of Manual. Under this heading your Committee first invites your attention to pages 420 and 421 of the report where revision of six paragraphs of the section of the Manual covering freight yards is recommended, namely paragraphs (1), (5), (23), (25), (28) and (50). The present and proposed forms of these items are shown in the report. Your Committee recommends, and I move the adoption of the six paragraphs named in their proposed form in lieu of the present form.

(The motion was put to a vote and carried.)

Chairman M. J. J. Harrison:—Your Committee now invites your attention to pages 421 to 434 of its report where a general revision of the section of the Manual entitled Rules for the Location, Maintenance, Operation and Testing of Railway Track Scales is recommended.

By way of explanation, your Committee has been working for some few years with the aim of getting this material in acceptable form. Furthermore, at the present time the Traffic Division of the American Railway Association, through its Committee on the Weighing and Inspection of Freight Traffic, is most anxious to reissue in pamphlet form these rules, for which, in the present scheme of organization, it must depend on this Association. To enable the Traffic Division to reissue its pamphlet, your Committee has made a critical review of this entire section of the Manual and recommends for adoption the material shown under the heading Proposed Form in this portion of its report.

In Section I—Location, certain minor changes are proposed as shown.

In Section II—Maintenance and Operation, the same comment applies.

In Section III—Testing, a revision of the first paragraph and the deletion of present paragraphs 2 and 5 are proposed, the material contained therein being included elsewhere in the proposed form.

In Section IV—Equipment for Testing, certain minor changes are proposed as shown in the report. In addition to the form shown on page 426, and prompted by one of the letters of comment recently received by the Committee, your Committee proposes to insert in the seventh line of Paragraph 1, near the top of the page under Proposed Form, and following the word “cars”, in parentheses “See Item 2-b Section 6 hereof,” making that entire sentence read: “The working standards used in compartment type test weight cars (see Item 2-b, Section 6 hereof) should be rectangular and of such design as to facilitate stacking.”

Former Section V was withdrawn from the Manual by action of the 1931 convention. The material here proposed as a new Section V—Definition of a Standard Test of a Railway Track Scale, was presented to the 1933 convention as information. During the past year your Committee has reviewed this material and has concluded to recommend certain revisions in paragraphs 6 and 8 thereof. These two paragraphs are shown on pages 426, 427 and 428 of the report, the columns headed Present Form being the material submitted as information a year ago. Paragraphs 1, 2, 3, 4, 5 and 7 of this section are shown on pages 433 and 434 of the report, and no change from the form in which they were presented as information is now proposed by your Committee.

There is a typographical error, the fault of which lies with your Committee Chairman, in the last line on page 426. The first full word in that line under Proposed Form reads now “disconnected” and it should read “connected.”

Section VI—Specifications for Railway Track Scale Test Weight Cars. This section was adopted as Manual material by the 1933 convention and is included here by reference only. No revision of this section is now proposed by your Committee.

In lieu of old Section VII—Test Weight Cars, an entirely new Section VII—Rules for Maintenance and Transportation of Track Scale Test Weight Cars is proposed. This new material was submitted as information at the 1933 convention, and no revision of that form is now proposed by your Committee.

Section VIII is proposed to stand with the present wording, with the addition of a number identifying it as a section of these rules.

Your Committee recommends, and I move, the adoption of the proposed form of this section of the Manual to replace existing Manual material as indicated in the report and with the corrections I have just mentioned.

The President:—You have heard the motion. It is now before you for discussion. This is rather a lengthy report and we should have some discussion upon it. It is a very important one. I will ask the Chairman to offer each section of it by title to the convention for discussion and revision or amendments to the subject-matter.

Chairman M. J. J. Harrison:—Rules for the Location, Maintenance, Operation and Testing of Railway Track Scales—

Section I—Location:

1. General Conditions.
2. Alinement of Live and Dead Rails.
3. Gradients for Motion Weighing.
4. Runoff Gradient for Spot Weighing.

Section II—Maintenance and Operation:

1. Numbering Scales.
2. Scale Shop.
3. Cleaning.
4. Rust Preventive for Pivot and Bearing Steels.
5. Removal of Ice.
6. Standing of Equipment Prohibited.
7. Restriction to Use of Live Rails.
8. Cars Restricted to Live Rails or Dead Rails Only.
9. Use of Sand and Injector.
10. Weigh-beam.
11. Stopping Cars on Scales.
12. Automatic Weighing and Recording.
13. Locking Scale Houses.
14. Inspection by Weighmaster.
15. Painting.

Section III—Testing:

1. Test Frequency.
2. Weekly Tests.
3. Daily Tests.

Section IV—Equipment for Testing:

1. Standard of Mass.
2. Even Arm Balance and Master Scale.

Section V—Definition of a Standard Test of a Railway Track Scale, and here we turn for continuity to page 433:

1. Test Equipment.
2. Test Car Positions.
3. Zero Load Balance.
4. Sensibility-Reciprocal.
5. Classification of Tests.
6. Scales with Automatic Weight Recording Attachments.
7. Test Record.
8. Tolerances.

Section VI—Specifications for Railway Track Scale Test Weight Cars. This is material which now appears in Bulletin 356 and is included here only by reference.

Section VII—Rules for Maintenance and Transportation of Track Scale Test Weight Cars:

1. Classification.
2. Weight Control.
3. Transportation.

Section VIII—Disposition of Obsolete Track Scales.

The President:—I should like to have some discussion on this very valuable report.

Chairman M. J. J. Harrison:—I might say that the Committee has received in the last two or three days rather extended written discussions from three members of the Association covering various points included here. As already stated, the Committee is very appreciative of these comments. They will be taken under careful advisement by the Committee.

The President:—Are you ready for the question? The question is on the adoption and printing in the Manual of these specifications as revised. All those in favor will signify by saying "aye"; contrary. It is carried and so ordered.

Chairman M. J. J. Harrison:—The matter of withdrawal of the section of the Manual entitled "Specifications for the Manufacture and Installation of Motor Truck, Built-in, Self-Contained and Portable Scales for Railway Service" will be handled as a part of the Committee's report on its assignment No. 5, Scales Used in Railway Service.

Our assignment No. 2 is Grain Elevator Storage Yards and Plant Tracks. The report will be presented by Mr. W. H. Giles, Chairman of the Sub-Committee.

Mr. W. H. Giles (Missouri Pacific):—The report of Sub-Committee (2), Grain Elevator Storage Yards and Plant Tracks, will be found in Bulletin 361, page 434. The information contained in the report has been assembled after study of replies to questionnaires sent to various railroads. The three general types of elevator plants served by the railroads are mentioned and a brief description of the plant tracks included.

The characteristics of plants as reported are shown in the statement on pages 438 and 439. An example of a rail to rail plant is shown in Fig. 1 at page 436, and Fig. 2 on page 440 shows a rail to water plant.

It is recommended that the report be received as information.

The President:—Is there any objection to receiving this report as information? If not, it will be so received.

Chairman M. J. J. Harrison:—Assignment (3) is Hump Yards. The report will be presented by Mr. E. M. Hastings, Chairman of the Sub-Committee.

Mr. E. M. Hastings (Richmond, Fredericksburg & Potomac):—You will find the report of this Sub-Committee on page 441 of Bulletin 361.

This report is a further discussion of the graphic method to be used in designing gradients in connection with the application of car retarders to hump yard operation, particularly concerning application under Graphic Method "B", a discussion of which was presented to the 1933 convention. The report which is now presented completes the discussion of the graphic method of design. It is intended only to describe the methods so that anyone desiring to use these graphic methods may have full information as to their application. There are no conclusions to be drawn. The discussion in the report is presented for the information of the Association.

The President:—They will be accepted as information. If anyone wishes to discuss these reports that are to be accepted as information, we will be glad to have them rise and take part in the proceedings.

Chairman M. J. J. Harrison:—Assignment (5) is Scales Used in Railway Service. The report on this subject will be presented by Mr. H. M. Roeser, Chairman of the Sub-Committee.

Mr. H. M. Roeser (Howe Scale Company):—This report has to do with Appendix D on page 447, Bulletin 361, and has for its purpose revision of Specifications for the Manufacture and Installation of Motor Truck, Built-in, Self-Contained and Portable Scales for Railway Service now in the Manual beginning on page 1034. The public has shown a tendency to generally depend on these specifications, and thus they

have come to have the standing of a monument of professional merit of the Association in fixing standards not only for the purpose of the transportation industry but for others.

To add security to that phase of the activity, as well as to add clarifying and completing features the specifications have always lacked, the assignment became desirable at this time.

Completing the assignment during the past year was found impossible. However, interest in the developments had become such that, by the time of the fall meeting, the Committee decided to recommend deletion from the Manual of the specifications, and publication of the work so far completed in the Proceedings as information. Subsequently, opportunity was found to forge a bit further ahead, but at that time Bulletin 361 had been printed. We then concluded upon making the complete action to date available by proposing the supplemental report just now distributed among you.

We will have to apologize for the ragged form in which this report is presented. It represents, first, our desire to get on record with the progress to date, and, second, it reflects the impossibility of completing the assignment within the past year.

I shall not dilate upon it except in so far as that required in the action now proposed. I want to offer two motions, the first of which is to move deletion from the Manual the subject-matter beginning on page 1034 under the caption "Specifications for the Manufacture and Installation of Motor Truck, Built-in, Self-Contained and Portable Scales for Railway Service."

The President:—It has been moved and seconded that the subject-matter on page 1034 of the Manual, Specifications for the Manufacture and Installation of Motor Truck, Built-in, Self-Contained and Portable Scales for Railway Service be deleted from the Manual. Is there any discussion? All those in favor say "aye"; contrary. It is carried and so ordered.

Mr. H. M. Roeser:—The action to be proposed is a little unusual, but at the direction of the Committee I move the publication as information of the work thus far completed on the assignment of revising the Specifications for Motor Truck, Built-in, Self-Contained and Portable Scales for Railway Service, the same to serve ad interim the purpose of the material on the same subject deleted from the Manual by the action taken on the last motion.

The President:—You have heard the motion to print in the Proceedings. All the reports that are submitted as information are printed in the Proceedings. The Committee, I take it, wants to add a little emphasis to this report and call the attention of the members to the fact that it is in shape to be used but that they are not quite ready to recommend it for the Manual. Is that correct?

Mr. H. M. Roeser:—Yes.

The President:—Is there any discussion on this report? All those in favor say "aye"; contrary. It is carried.

Chairman M. J. J. Harrison:—On assignment (6) Bibliography on Subjects Pertaining to Yards and Terminals, I will ask Mr. Tratman, Chairman of the Sub-Committee, to present this report. The Committee again desires to record its appreciation of Mr. Tratman's efforts in compiling this Bibliography, which we feel was quite worth while.

Mr. E. E. R. Tratman (Civil Engineer):—As to the Bibliography, there is not much to say. The Committee has got together a lot of information which it hopes may be of use. There is one point to which I might call attention. In the great variety of subjects included in the Bibliography, besides the list of individual yards and passenger terminals, you will find such items as city planning, valuation, switching charges, and

so forth. Those, of course, have more to do with operation, but the work of this Association includes both engineering work and operating work. They illustrate also the variety of subjects involved in yard and terminal problems.

Another point is as to the quantity. Owing to my leaving for Europe in July, this printed list only comes down to last June. I am now working on the remainder of it, and I hope that the list printed in the next report of the Committee will be very much longer than this.

There is just one other point. You will notice some items as to the container system. In England I was much surprised at the great extent of the use of containers, but their use is very much simpler in that country because 90 per cent, possibly 95 per cent of their cars are only of eight or ten tons capacity. Therefore, the single container makes a single carload, while here we usually have to put six or eight or more containers on a car to make a good load. Finally, I can only say we hope that members of the Association will find some use for these bibliographic lists.

The President:—This Bibliography will be printed in the Proceedings.

Chairman M. J. J. Harrison:—Assignment (7) Expediting of Freight Car Movements through Yards. The report on this subject will be presented by Mr. W. F. Cummings, Chairman of the Sub-Committee.

Mr. W. F. Cummings (Boston & Maine):—The report of Sub-Committee (7) the Expediting of Freight Car Movements Through Yards, is shown on pages 466 to 472, both inclusive, of Bulletin 361. The report of the Committee this year has been confined to statements to show the importance of the subject and a listing of some of the facilities which will help in its solution.

The Committee intends, if the assignment is continued, to study the more specific phases of the subject. The report is offered as information with a request that the subject be continued.

The President:—Is there any discussion on this report? The Committee would like to have expressions of opinion on all these reports that are offered as information. The report will be received as information and printed in the Proceedings.

Chairman M. J. J. Harrison:—If I may supplement what you said, the Committee would be very appreciative of any written discussions that any of the members might have to offer.

This concludes the report of the Committee on Yards and Terminals.

The President:—The information presented by this Committee is timely and valuable, and we will now excuse them with the thanks of the Association (Applause).

Mr. C. E. Smith (Vice-President, New York, New Haven & Hartford—by letter):—This Committee has had a long and creditable career, which is being continued by its present personnel. Much good work has been done. The latest report is one of the best. Every railroad man should appreciate the opportunity of having such information prepared for him by the Committee.

Mr. Charles H. Blackman (Principal Assistant Engineer, Louisville & Nashville—by letter):—I have gone over this report very carefully, and take this opportunity to congratulate the Committee on having done some good work.

There are, of course, some minor changes and corrections that the Committee itself will no doubt make after giving it further consideration.

For instance, in the proposed revision of specified items covering freight yards, paragraph 5-(d) could, I think, be omitted entirely. In paragraph 28, three words could be omitted, making a part of the sentence read—"move directly to the departure tracks".

Under the Rules for Location of Track Scales, I am not at all in accord with the statement in Section 1, paragraph 1-(a). The presence of the scale in a much-used track does add to the maintenance, inspection and testing troubles, but I do not see that it is particularly dangerous to trainmen.

In the old form of this paragraph, the 60 per cent requirement of cars to be weighed in proportion to total number of cars handled applied only to flat yards, but in the proposed revision you are making this applicable to all yards. In a hump yard, I think the scale should be on the hump if even as much as 20 per cent of the cars are to be weighed, for otherwise these cars would need to be dropped into a special classification track for weigh cars and then rehumpped for classification after weighing. There are no points on our line, other than assembling yards in the mine districts, where anything like 60 per cent of the cars passing through the yard need to be weighed.

With reference to paragraph 1-(c) of Section 1, I beg to say that we have points where the scale is located on an inner body track, tracks being spaced on wide centers to permit such installation. I agree that it is not economical.

The specifications given in Appendix D would seem from the wording to have been prepared by or in co-operation with some manufacturers committee. I would suggest that such paragraphs be eliminated before the specifications be adopted for publication in our Manual.

As a matter of fact, the importance of scales of this type would not justify the average railroad in making the inspection necessary to see that the scales were manufactured in compliance with specifications of this type, and, in fact, if we undertook to purchase to these specifications, we would simply ask the manufacturer to state whether the scales did or did not comply with these specifications.

In Appendix F, I note that the Sub-Committee realizes the importance of its subject, although its report for this year simply consists of a statement of the problem. The problem is one on which the future existence of the railroads depends, and it would seem that it might be given jointly to the Yards and Terminals Committee and the Committee on Economics of Railway Operation, and if these committees can offer any constructive suggestions to our operating and managing officers they will have performed a service of enormous value to the railroads.

Mr. Benj. Elkind (Erie Railroad—by letter):—I have reviewed this report and have no comments to make, other than to suggest that on page 421, under paragraph 'c' in connection with length of a scale track which is also a body track, the scale track should extend the length from the scale in both directions to clear the longest cut of cars to be weighed instead of "it should be twice as long as the longest cut of cars to be weighed".

Mr. H. M. Stout (Northern Pacific—by letter):—In going over this report and discussing portions, it has been observed the tolerances which are included in the proposed revision of the Manual under the title, "Proposed Revision of Rules for the Location, Maintenance, Operation and Testing of Railway Track Scales," are greater in several rather important instances than are permitted in our practice.

Of course, you are acquainted with the "Specifications for the Manufacture and Installation of Railroad Track Scales", approved by the Minnesota Railroad and Warehouse Commission, effective in the State of Minnesota since June 1, 1920, which were prepared, except for some additions, by a committee appointed by R. H. Aishton, then Northwestern Regional Director of Railroads of the Federal Administration of Railroads, representing (1) the American Railroad Association, (2) the American Railway Engineering Association, (3) the United States Bureau of Standards, (4) the Railroad and Warehouse Commission of Minnesota, (5) the National Scale Men's Association,

and (6) the Scale Manufacturers' Association. The requirements of these specifications are more exacting than those of most States having established rules governing these matters. So far as is known, our scales are all maintained, throughout the seven Northwestern States which our lines serve, within the tolerances of the Minnesota specifications, although in some of them the supervision and requirements of the State authority make minimum demands upon the railroads as to the condition of scales.

Comparing our practice with the proposed revised specifications for the Manual of your report, the following are noted:

Section III—Testing; paragraph 5: A maximum error of two pounds per thousand is allowed, whereas our requirements permit but one pound per thousand.

Section V—Definition of a Standard Test of a Railway Track Scale; 8—Tolerances.—(1) Maintenance Tolerances, paragraphs (a), (b) and (c): In each case, the tolerance is 2/10 of 1 per cent, or 2 lb. per 1000 lb. of test load, whereas our requirements are 1/10 of 1 per cent, or 1 lb. per 1000 lb. of test load.

Section VII—Rules for Maintenance and Transportation of Track Scale Test Weight Cars; (2) Weight Control.—(c) Frequency of Verification Recommended.—(3) Verification of Terminal Test Weight Cars: Instead of the minimum of twice yearly of your specifications, our requirements are four times per year, or 2500 miles.

Although not specifically stated in the Minnesota specifications, the inspectors for the M.R.R.&W.C. recommend the live rail be the straight rail in any track scale installation, and the dead rail be the offset rail. This is to eliminate the pull of heavily loaded and stiff cars while on the scale. This is the reverse of the Committee's specification, Section I, paragraph 2—Position of Live and Dead Rail.

The Minnesota Railroad and Warehouse Commission have not prepared any specifications for the construction, installation and maintenance of scales for motor trucks and other uses in railway service, nor have other of our States provided specific regulations for them, comparable with the specifications submitted in Appendix D of your Committee's report.

I am of the opinion the discussion of the Committee on the three subjects under study as given in appendices

(B) Grain Elevator Storage Yards and Plant Tracks,

(C) Hump Yards,

(E) Bibliography of Subjects, pertaining to Yards and Terminals appearing in Current Periodicals, constitute valuable contributions to the study of the modern railway yard, and Appendix F—The Expediting of Freight Car Movements through Yards—is a commendable approach to and statement of the problem.

The Federal Coordinator of Transportation, in his first and preliminary report to the Interstate Commerce Commission, and through them to the President and the Congress, has made repeated references to the operating costs of railroad terminals. I apprehend the Committee may find much of interest in the studies and investigations which have been made and are being carried on by the Coordinator and research under him and which, he complains, although worthy of publication, lack of funds will not permit. He has said, however, the information gathered has been assembled in convenient form for reference purposes.

Mr. B. T. Anderson (Union Switch and Signal Company—by letter):—I was particularly interested in this report, and especially in those sections of it relative to hump yards and expediting the freight car movements through yards, as these sections refer particularly to car retarders and signaling, in which I am very much interested.

The Committee is presenting a well-prepared report, and they are to be congratulated on the manner in which the subject has been covered.

I have no exceptions to take to this report, and feel that it should be presented to the Association as prepared.

Mr. Hadley Baldwin (Cleveland, Cincinnati, Chicago & St. Louis—by letter):—I have read through the report of the Yards and Terminals Committee, appearing in Bulletin 361, with much interest. It is a fine report, such as manifestly requires much valuable time and exhaustive analysis.

I may refer particularly to the recommendations of Sub-Committees 1 and 5 as dealing with the general subject of scales. Having myself participated rather strenuously, though enjoyably, in what perhaps may be characterized as the Association's original thoroughgoing treatment of this subject at the hands of the Yards and Terminals Committee, I have maintained a rather special interest in the continued efforts of the Committee which have refined and expanded the significance of what was in the beginning brought forth.

More for the sake of feeling for the moment as if I were again a member of the old Committee than because of any probable necessity, and at the risk of showing that my knife-edges have grown a little dull or rusty, I am going modestly to append a few comments on the proposed revision of "Rules for the Location, Maintenance, Operation and Testing of Railway Track Scales," as follows:

Section I—Location. 1-(a) The expression "except in special cases" seems to make it necessary to consider a hump scale a special case, which might not be generally understood. 1-(e) It would be better, I think, to insert "otherwise" after the word "when", and I think I would go so far as to substitute the word "might" for the word "would" in the last line. 2. The new definition is less inclusive than the old.

Section II—10. The word "maximal" is OK, but was a new one to me.

Section IV—1. The nominal value of working standards is not designated, but apparently should be, as basis for the tolerance prescribed.

Section V—6. Apparently the word "connected" should be substituted for the word "disconnected" at end of first sentence.

3-(a) It would appear that the word "more" should be substituted for the word "less" at the end of the fifth line.

In view of my present remote contact, I cannot recruit the temerity to undertake any exhaustive estimate of the technique of the reports in question. It required maximal effort for me to keep up with tolerance when I was in the heat of conflicting opinions that our earlier wrestling with the major and microscopic issues of scale etiquette seemed properly to engender.

I'll bet, though, that the boys' conclusions are all right, or anyway that they are better than ever.

Col. F. W. Green (St. Louis—Southwestern—by letter):—A reading of this report impresses me with the fact that the Committee's proposals in a number of instances will result in changes that will be beneficial to the railways. The report also elaborates and amplifies the present information in other instances.

The Committee is to be complimented on its work. It accomplished what it endeavored to do, which was to produce a worth-while report.

Mr. S. S. Roberts (Assistant Director of Finance, I.C.C.—by letter):—I regret that business at the office and personal business that required immediate attention have prevented my reading the entire report of the Committee. I have, however, read in a cursory manner that part of its report concerning the selection of gradients for retarder operated hump yards.

Since it is probable that no two cars will roll exactly alike, and that the same car will roll differently under different conditions of weather and of lading, no rule or for-

mula will give reliable results under all conditions. I have found that by the use of velocity-heads and car resistance there will be obtained as reliable indications of speed and gradients necessary to produce these speeds as by the use of any other method.

In the design of hump yards, I have endeavored to obtain sufficient fall from the top of the hump to the tail end of the yard so that a slow rolling car would roll to clearance at the tail end of the yard, and I depended on the car riders to so control the speed of easier rolling cars by the use of hand brakes, that such cars would roll to coupling without damage to the car or contents. The introduction of car retarders transfers the responsibility for the speed of the easy rolling cars from the car riders to the tower man who operates the retarders. Although the introduction of car retarders requires a different track layout and arrangement of ladders at the head end of the yard, the outstanding difference between the hump yard operated by car riders and that operated by retarders is that mentioned above.

In hump yard designs that I have made in the past I held the gradients of the track, or the two tracks, through the center of the yard and the gradients of the two outside tracks of the yard as controlling the gradients of the intervening tracks. It is not clear to me why the introduction of car retarders should cause a departure from the above procedure.

I here call your attention to my letters of February 9 and February 16, 1933, to Mr. E. M. Hastings, Chairman, Sub-Committee 6, Hump Yards, Committee XIV, together with the photostats of suggested head end plan for retarder operated classification yard which accompanied these letters. I have not been advised by the Committee whether it found any merit in the plan I suggested. My past experience leads me to believe, until I am otherwise convinced by facts that are not now within my knowledge, that the plans I suggested have merit. Under these plans the gradients for the two tracks through the center of the yard and the gradients for the two tracks on the outside of the yard should be controlling. The body tracks of the yard should have substantially the same gradients. The elevations of each succeeding body track from the center of the yard to the outside track should be proportionately lower than the elevation of the track through the center. The surface between the tracks between the center and the outside tracks at the head end of the yard on which rests the switch leads and the car retarders may be a warped surface, but the surface of the entire yard will generally fall from the hump toward the tail end of the yard and crosswise from the center tracks to the outside tracks, except that toward the tail end of the yard there should be generally a light rising gradient to bring the cars to rest at or before they reach the clearance point.

In attacking the problem of determination of gradients for such a yard, it seems to me now that I should design gradients from the top of the hump along the two center tracks of the yard and from the top of the hump along the two outside tracks of the yard so that the slowest rolling car would roll to clearance with all of the retarders open, that is, inactive, and then select the proper number of retarders located in the most effective places to so control the speed of the easier rolling cars so that the easiest rolling car should come to rest at or before reaching the clearance point at the tail end of the yard. The gradients of the tracks intermediate between the center tracks and the outside tracks should automatically take care of themselves.

In my opinion, the time spacing of cars in the car rider hump yard is controlled principally by the engineer of the hump engine, the man who cuts the cars at the hump, and the car riders. In the retarder operated yard the retarders are substituted for the car riders. In considering speeds, no slow rolling car should attain a speed so great as to cause danger of derailment on the switch leads or on the curves when all of the re-

tarders are open, or inoperative, and no easy rolling car should attain a speed so great that it could not be brought to rest by a retarder without damage to the car or contents. Thus, in designing the gradients at the head end of the yard, consideration must be given to the capacity of the car retarders and to the frequency of their insertion as determined by their capacity.

I have not the time nor the facilities, for drawing the head end plan I suggested, using a number 8, 9, or 10 frog. I should think it would be worth-while for the Committee to either make such a drawing or to compute the horizontal distances that would be required for such a yard with a frog of practical number from which it should be possible to determine whether or not gradients of practical use could be applied to it.

In my opinion, the plan I suggested in February, 1933, lends itself to a practicable development of gradients both for speed and for drainage purposes.

Mr. F. L. C. Bond (Canadian National Railways—by letter):—In reviewing the various reports as submitted by the Sub-Committee, I find that this Committee has been assigned subjects which are of great interest to the railways, especially at this time with present business conditions and trucking competition, making it essential that our freight traffic be moved as speedily and economically as possible. The report on the Expediting of Freight Car Movements Through Yards is particularly important and instructive and undoubtedly the study of this subject should be continued as its solution will solve one of our major transportation problems.

The report clearly indicates that a great deal of study and effort has been given by the members of the Committee and they certainly should be complimented on their excellent work.

## DISCUSSION ON RULES AND ORGANIZATION

(For Report, see pp. 521-528)

Mr. E. H. Barnhart (Baltimore & Ohio):—You will find the report of Committee XII in Bulletin 361 beginning on page 521.

For several years this Committee has collaborated with Committee XI—Records and Accounts in the preparation of bridge inspection forms.

In order to bring the subject-matter now in the Manual covering bridge inspection in conformity with the revised forms which Committee XI will recommend for adoption, a revision of several paragraphs is necessary. The report of the Sub-Committee on Revision of the Manual will be presented by Mr. Coons, Chairman of the Sub-Committee.

Mr. P. D. Coons (Burlington):—The revision just referred to will be found on page 522 of Bulletin 361. The recommended changes cover three numbered rules, 1353 and 1359, and the elimination of 1415.

I move the recommended changes be approved.

The President:—It is moved and seconded that these rules be revised as shown in the proposed form on page 522 of the Bulletin. The question is now before you for discussion. All those in favor of this motion will signify by saying "aye"; contrary. It is carried.

Chairman E. H. Barnhart:—Rules for Maintenance of Bridges—Masonry have been before the Association for the past two years. Last year these rules were referred back to the Committee for certain revisions. The revisions have been made and the report of this Sub-Committee will now be presented by Mr. Griggs, the Chairman of the Sub-Committee.

Mr. A. B. Griggs (Santa Fe):—The report of the Sub-Committee on Maintenance of Bridges appears in Bulletin 361, page 522 under Appendix B. The report consists of Rules 1150 to 1164, inclusive. The Committee's report has been under study for about two years, and the rules here submitted are the result after giving consideration to all of the suggestions offered to the report which was before the convention last year.

The rules have the approval of Committee VIII—Masonry and of Committee XV—Iron and Steel Structures. I move that Rules 1150 to 1164, inclusive, be adopted for printing in the Manual as recommended practice.

The President:—The motion is before you to adopt Rules 1150 to 1164, inclusive, as recommended practice and for printing in the Manual. The matter is now open for discussion. Are there any suggested revisions? All those in favor of the motion will signify by saying "aye"; contrary. It is carried and so ordered.

Chairman E. H. Barnhart:—For the past five years this Committee has had assigned to it the preparation of rules covering maintenance of telegraph and telephone lines and appurtenances. You will find in Appendix C the rules which have been proposed. These rules have been prepared by a Sub-Committee of the T&T Section and are submitted as particularly applying to Maintenance of Way employees. The Committee requests that members of the Association who are interested in this phase of maintenance of way work, carefully go over these rules and submit to the Committee any criticism or suggestions.

The Committee offers the rules in Appendix C as information.

The President:—Is there any discussion on this subject? The matter will be received as information and printed in the Proceedings.

Chairman E. H. Barnhart:—Last year the Committee presented as information appropriate titles for the position known as Assistant Engineer, in all departments. Mr. Brooke and his Sub-Committee have spent considerable time and study in obtaining this data. Unfortunately, Mr. Brooke is unable to be present this morning, on account of illness, to present his report. The report of the Sub-Committee will therefore be presented by Mr. Warden, the Vice-Chairman of the Committee.

Mr. R. E. Warden (Missouri Pacific):—The Committee submitted as information last year appropriate titles for Assistant Engineers, in all departments. This information was collected after considerable investigation and study, and the membership was appealed to for criticisms and suggestions. Since the submission of this information, no criticism or suggestions have been received. The Committee, therefore, submits, in Appendix D, these titles for approval and printing in the Manual.

These titles are found on page 526. I move that they be accepted and printed in the Manual.

The President:—It has been moved and seconded that these titles as shown on pages 526 and 527 of the Bulletin be approved and printed in the Manual. Is there any discussion on these titles? All those in favor please say "aye"; contrary. It is carried and so ordered.

Chairman E. H. Barnhart:—The report of Sub-Committee (4), Rules for Fire Prevention as Applying to Maintenance of Way Department, will be presented by Mr. Hayes, the Chairman of the Sub-Committee.

Mr. H. C. Hayes (Illinois Central):—The subject assigned to Sub-Committee (4), Rules for Fire Prevention as Applying to Maintenance of Way Department, has been before this Committee for five years. These rules as now proposed are to be found on pages 527 and 528 of Bulletin 361. They cover the divisional supervisory officers only and are not to be considered as covering the whole subject of fire prevention.

These rules presented are the result of a questionnaire and represent the general practice of the majority of the railroads represented in this Association. They were presented last year as information, since which time they have been revised and rearranged in compliance with criticisms and suggestions received at the 1933 convention and subsequent letters. They have been approved by the National Board of Fire Underwriters and the Railway Fire Protection Association.

I move that the rules as offered in Appendix E be approved for printing in the Manual.

The President:—The question before you is the adoption of the rules printed on pages 427 and 428 and the printing of them in the Manual. I am going to ask the Chairman to present each article for discussion and amendment, giving an opportunity for discussion after the reading of each one.

Mr. H. C. Hayes:—Under General Rules: "33. Employees must give full cooperation to fire prevention measures and be familiar with location and use of nearest fire alarms.

"Division Engineers: 302. They must see that employees under their jurisdiction are properly instructed in fire prevention rules, alert in decreasing fire hazards and exacting in the maintenance and operation of fire fighting apparatus. When locating buildings and structures, they will see that attention is given fire prevention.

"Supervisors of Track: 316. They must give particular attention to fire hazards from adjoining property and from structures erected on railway property by lessees.

"317. They must see that those under their supervision do not obstruct fire roads, fire hydrants and hose houses.

"318. They must see that no lumber, ties, piling or other inflammable materials are piled in close proximity to any important building and that automobiles or trucks are not parked in a manner which constitutes a fire hazard.

"319. They must know that their foremen understand and observe fire prevention rules.

"Supervisors of Bridges and Buildings:

"374. They must give particular attention to fire hazards where the risk is extreme, such as oil houses, paint shops, wood coal chutes, and cotton platforms.

"375. They must make proper reports to superiors of any unguarded fire hazards.

"376. They must see that those under their supervision do not obstruct fire escapes and exit passages thereto, fire doors, hose reels, fire hydrants, fire roads, and hose houses.

"377. They must see that all sprinkler systems and fire fighting apparatus under their jurisdiction are maintained in accordance with the National Fire Underwriters Code.

"378. They must arrange through their superior officers for the proper cooperation of all municipal fire departments.

"379. They must make recommendations for fire stops when necessary, and for the removal of any fire hazards.

"379-A. They must see that inflammable materials are stored so as to confine any fire to the place of origin.

"379-B. They must know that their foremen understand and observe fire prevention rules.

"Supervisors of Water Service: 423. They must know that fire pumps and fire lines under their jurisdiction are in proper working condition, and that fire hydrants and hose are always ready for instant use.

"424. They must call attention to points where connections might be made to municipal fire mains.

"425. They must know that their foremen understand and observe fire prevention rules."

The President:—Is there any discussion on these rules? If not, all those in favor of the motion to adopt them as recommended practice and for printing in the Manual will say "aye"; contrary. It is carried and so ordered.

This Committee has done a very valuable work this year, and we will now dismiss them with the thanks of the Association (Applause).

## DISCUSSION ON RECORDS AND ACCOUNTS

(For Report, see pp. 579-620)

Mr. C. C. Haire (Illinois Central):—The report of the Committee is the first one in Bulletin 362, page 579. There are fourteen assignments that have been given to us to handle during the year. Reports for eleven of the subjects are included in the Bulletin, and progress is reported on three.

Our first subject under Group A—Miscellaneous, Revision of Manual (Appendix A) will be presented by Mr. Butler in the absence of Mr. Smith, the Chairman of the Sub-Committee.

Mr. E. S. Butler (Kansas City Southern):—The report of this Sub-Committee will be found on page 580 in Bulletin 362. It has to do with the revision of the Manual, and the Committee recommends the adoption of these changes. Should they be read?

The President:—Yes. I will be glad to have you read the proposed form.

Mr. E. S. Butler:—The present form is found on pages 726 and 727, paragraphs 6 and 7, of the Manual. It has to do with Equipment Completion Report, Form 1118, and the recommendation is that that be omitted from the Manual.

The next is Labor and General Forms, Time Roll, Form 1119. There is a change proposed in that. The proposed form is: "Carriers are constantly striving to get the maximum worth of the maintenance dollar. They should be able to show that their expenses are efficiently and economically handled as a matter of sound business practice."

I move the adoption of these changes in the Manual.

The President:—It has been moved and seconded that Specifications for Form 1118 be omitted, and that Form 1119 be revised. Is there any discussion on this subject? If not, all those in favor will say "aye"; contrary. It is carried and so ordered.

Chairman C. C. Haire:—I might say, in connection with your statement made this morning, that it is the intention of the Committee under this assignment which is given us annually, to make a comprehensive study of all its material to develop a program so that when and if necessary, the entire section of the Manual devoted to Committee XI can be revised concurrently with the change in practice that may be brought about by the issuance of the new classification of accounts, depreciation order and a modified valuation procedure. We are attempting to establish this objective and work out a more modernized practice for our section of the Manual.

The next assignment given to the Committee is the one on Bibliography for subjects pertaining to records and accounts. Mr. Weymouth, Chairman of the Sub-Committee, will present the report.

Mr. A. P. Weymouth (Pennsylvania):—The report of this Sub-Committee on Bibliography is found on pages 581 to 583 of Bulletin 362. This is one of our continuing subjects, and the report has been prepared in the same manner as in previous years. We present a bibliographical review of important books and articles pertaining to records and accounts. It covers the period from November, 1932, to October, 1933, inclusive. The report is submitted as information, and the subject will be continued.

The President:—The report will be so received and printed in the Proceedings.

Chairman C. C. Haire:—Our next subject is Office and Drafting Room Practices (Appendix C). This is quite a lengthy report, and I hope it has received your attention since the Bulletin was published. It is one that is being constantly modified, and the Committee is always glad to receive any suggestions. In fact, we received quite a few from the signal people. The Chairman of the Sub-Committee, Mr. Avery, will present the report and will tell you about those changes.

Mr. D. L. Avery (Chesapeake & Ohio):—This is a report of Sub-Committee (B-1) Drawing and Drafting Room Practice. The report will be found in Bulletin 362, pages 583 to 602, inclusive.

The Committee devoted most of its time during the year to preparing a pamphlet covering electrical and signal symbols. At the request of Committee X—Signals and Interlocking and Committee XVIII—Electricity, it was decided to discontinue work pertaining to their symbols.

Last year's report of the Committee has been revised to include constructive suggestions and additions offered during the year.

It is recommended that the symbols shown on page 589 under Track Fixtures and the line of index referring to Track Fixtures on pages 584 and 585 be omitted from this report tentatively. The reason for that is this: It is the intention of the Committee to collaborate further with the Signal Section, separating signal from track symbols.

With this omission it is recommended that the graphical symbols submitted herewith in Bulletin 362, pages 584 to 602, inclusive, be approved for publication in the Manual in the place of those shown in the 1929 Manual, pages 745 to 757, inclusive, with this exception: The title, which was omitted by the printer, Drawing and Drafting Room Practice, Graphical Symbols, should be shown at the top of page 584, the beginning of the report.

I so move.

The President:—The motion is on the adoption of these symbols as recommended practice, for printing in the Manual, with the exception of Track Fixtures.

Mr. A. R. Wilson (Pennsylvania):—On page 597, at the bottom of the sheet, the proportions for rivet heads are shown. Committee XV has as its assignment Design of Rivet Heads. This Association has a member on the committee of the American Standards Association dealing with the same subject. The subject not having been concluded by either body, I think it unwise to present at the present time in the Manual proportions for rivet heads. I would leave the words "Grip" and "Length" as the definition, omitting any reference to the proportion of the head, either for buttonhead or countersunk rivets.

Mr. D. L. Avery:—It is the intention of the report to eliminate any reference to buttonhead or countersunk rivets. It was submitted in this form at the suggestion of Mr. Lang of Committee XV—Iron and Steel Structures.

Mr. J. C. Irwin (Boston & Albany):—I endorse Mr. Wilson's opinion in regard to stating any dimensions that might have an effect on the design of rivets. I see no objection to putting in a symbol which shows the manner in which they shall be indicated. Mr. Wilson is quite right in regard to the progressive work being done by the committee of the American Standards Association. It would not be the function of this Committee to have any influence on the design of rivets.

Mr. H. M. Stout (Northern Pacific):—It seems to me it would be appropriate for the Chairman of the Committee or the Chairman of the Sub-Committee at this point in the proceedings to indicate what contact or collaboration they have had with the American Standards Association. Some years ago the American Engineering Standards Committee, the former name of the A.S.A., had a committee working along this same line. The Association ought to know whether there is possible conflict between the two associations.

Mr. D. L. Avery:—This work is being prepared for the A.R.E.A. and also the A.S.A. These symbols will be submitted to the A.S.A. as recommended railroad practice if they are adopted at this convention, of course.

Mr. J. C. Irwin:—I think I might explain further that we have perfect collaboration on the question of symbols. The American Standards Association, of course, has committees on symbols, but Mr. Avery is our representative of the American Railway Association, Engineering Division. In addition to that we have representatives from the Signal Section and the Electrical Section on that same Committee on Symbols of the American Standards Association.

I think this is a progressive step, but what is produced here undoubtedly will have its influence on what action is taken in the American Standards Association committees. I see no objection to our approving what is presented by Mr. Avery, and I have no doubt that so far as the railway symbols are concerned that will be what will be adopted by the American Standards Association committee. Is that the question?

Mr. H. M. Stout:—Yes.

Mr. J. C. Irwin:—I think you have perfect coordination.

Mr. D. L. Avery:—Is it the intention of Mr. Wilson that we eliminate the symbol covering rivets?

Mr. A. R. Wilson:—I think it desirable to retain in the report the picture of the rivet, giving the definition of the word "Grip" and "Length", and it is unwise to continue in this report any reference to the dimensions of the rivet head.

Mr. D. L. Avery:—Eliminate all reference except "Length" and "Grip"? How about D, diameter?

Mr. A. R. Wilson:—I would show diameter. That applies to both the buttonhead and countersunk rivets.

Mr. D. L. Avery:—All other features of the rivet to be eliminated except those?

Mr. A. R. Wilson:—Any information that shows the proportion of the rivet head in reference to the diameter to be eliminated.

Mr. D. L. Avery:—The Committee accepts that change and will correct its plate accordingly.

The President:—Is there any further discussion? Are you ready for the question? The question is on the adoption of these symbols as recommended practice. All those in favor say "aye"; contrary. It is carried and so ordered.

This Sub-Committee is due a large amount of credit for the large amount of work they have done on this subject, and I think they are to be congratulated on their report (Applause).

Chairman C. C. Haire:—The next subject to be presented by the Committee is Joint Facility Records under Appendix D. In the absence of Mr. Bertenshaw, Chairman of the Sub-Committee, Mr. Powell will present the report.

Mr. A. T. Powell (Grand Trunk Western):—The report of the Sub-Committee on Joint Facility Records is found on pages 603 to 609 of Bulletin 362. This outlines the appraisal methods for determining rental base, includes a form on page 605, and outlines the methods for keeping the rental base up to date. On pages 606 and 607 it includes a chart and schedule of a typical jointly used facility, setting out the ownership, maintenance and operation. These will facilitate not only the proper carrying out of contracts in maintenance and operation but also facilitate proper billing between the carriers.

On page 609 the effect of the Depreciation Order on joint facility accounting is briefly outlined. If there are no comments, the Committee offers this report as information.

The President:—Is there any discussion on this report? It will be received as information unless there is some objection thereto. It is so received.

Chairman C. C. Haire:—The next subject to be presented by the Committee is Bridge Inspection Report Forms (Appendix E). This report appears on page 610, and I will make the report for the Sub-Committee. We made progress reports for the last three or four years on this subject. The matter of collaboration has been rather difficult as there are five committees involved in the design of these forms. The Committee offers three forms on pages 611, 612 and 613, which is, I might say, a compromise midway between considerable detail and a brief form of reports. The explanatory text on page 610 shows how these forms are to be used.

The Committee recommends that Forms 1110 Rev., 1110-A and 1110-B, together with the explanatory text on page 610 be approved by this convention for inclusion in the Manual. I so move.

The President:—It has been moved and seconded to adopt as recommended practice and for inclusion in the Manual the three forms as shown on pages 611, 612 and 613. Is there any discussion on these forms? If anyone has any revisions to suggest the Committee will be glad to have you so state.

Mr. W. A. Radspinner (Chesapeake & Ohio):—There is no reference made to water barrels.

Chairman C. C. Haire:—The Committee spent considerable time on these reports and secured most of the forms that were used by the railroads throughout the country. Some of you recall that they had previously been printed in the Proceedings as information, to which there was some objection as to the great amount of detail. Then, again, we designed a series of simpler reports, practically blank. Others raised the objection that there was not enough detail. So the five committees, through their representatives, attempted to strike a medium, and the forms presented here are the result. I think you will find that there are enough blank spaces, and the forms are flexible enough to include most of the detail.

My attention is called to the fact that on the form on page 611, near the bottom, water barrels and ladders are shown as an item.

The President:—Is there any further discussion? Are you ready for the question? All those in favor of adopting these three forms as recommended practice and for printing in the Manual say "aye"; contrary. It is carried and so ordered.

Chairman C. C. Haire:—Our next group of subjects is under Maintenance of Way Reports and Records. The first assignment under this group is (1) Statistical requirements of operating, accounting and other departments with respect to maintenance of way and structures. The report is shown under Appendix F, and Mr. W. F. Cummings will present the report of the Sub-Committee.

Mr. W. F. Cummings (Boston & Maine):—The report of Sub-Committee (C-1) of Committee XI is shown on pages 614 and 615 of Bulletin 362. This Sub-Committee is progressively studying and reporting as to forms and data outlined on the Chart of Accounting and Statistical Report Procedure in Maintenance of Way Departments shown on page 278, Vol. 27 of the Proceedings of this Association.

This year the Committee presents a form to cover the Recapitulation and Distribution of Material.

I ask that the report be received as information and that the subject be continued.

The President:—Are there any remarks on this report? It will be received as information and the subject continued.

Chairman C. C. Haire:—Under this same group of subjects the Committee presents a report under Appendix G dealing with railway water service records and forms. This subject has been with us for a number of years, and each year we have brought in a series of reports, one or more. We now bring the whole matter before you for

action on the part of this convention. I will ask Mr. Teal, the Chairman of the Sub-Committee, to present the report.

Mr. D. C. Teal (Chesapeake & Ohio):—The report will be found in Bulletin 362 on page 615. It consists of a summary of work done and recommendations regarding inclusion of new and the withdrawal of obsolete material from the Manual.

The work of the Committee has been to develop an up-to-date system of Water Supply Department forms to replace ones now appearing in the Manual. Forms now in common use have been collected and classified. Forms representing each general classification have been designed and presented to the Association during the past three years.

Forms presented are as follows: Cost of water production form presented in 1931; Monthly report of water station operation form presented in 1932; Quarter monthly report of water treating plant operation presented in 1933, and Record of water station facilities presented in 1933.

It is believed that the above forms together constitute an up-to-date system of essential water supply department forms that fulfill the requirements and cover the needs of present-day water service organizations.

The Committee recommends, and I move, that these forms be published in the Manual. The Committee recommends, and I move, that obsolete Water Service Department forms be withdrawn from the Manual.

The President:—I will ask that the Chairman make separate motions. There are four or five different subjects, and I would like to have them put before the convention separately.

Mr. D. C. Teal:—I move that Form 1302-Rev., together with text relative to same, as presented on pages 523 and 524 in Vol. 32 of the 1931 Proceedings, be published in the Manual.

The President:—The question is before you for discussion. These recommendations are relative to water service, and I wish Mr. Bardwell, if he has any suggestions, would please state them.

Mr. R. C. Bardwell (Chesapeake & Ohio):—Committee XIII—Water Service and Sanitation, have gone over these forms and worked in collaboration with this Committee, and the forms that have been presented during the previous years have received the endorsement of the Association. It is the opinion of Committee XIII that it is entirely proper that the present out-of-date forms now appearing in the Manual be eliminated and replaced by these forms which bring the information into much better shape.

The President:—Are you ready for the question? All those in favor say "aye"; contrary. It is carried.

Mr. D. C. Teal:—I move that Form 1302 appearing on page 956 of the 1929 Manual be withdrawn.

The President:—Is there any discussion? All those in favor say "aye"; contrary. It is carried.

Mr. D. C. Teal:—I move that Form 1301-Rev., together with text relative to same, as presented on pages 599 and 600 in Vol. 33 of the 1932 Proceedings, be published in the Manual.

The President:—Is there any discussion? All those in favor will vote "aye"; contrary. It is carried.

Mr. D. C. Teal:—I move that Form 1301 appearing on page 955 of the 1929 Manual be withdrawn.

The President:—Is there any discussion on this motion? All those in favor will vote "aye"; contrary. It is carried.

Mr. D. C. Teal:—I move that Form 1301-A, together with text relative to same, as presented on pages 239 and 240 in Vol. 34 of the 1933 Proceedings, be published in the Manual.

The President:—Is there any discussion on this motion? All those in favor say "aye"; contrary. It is carried.

Mr. D. C. Teal:—I move that Form 1303-Rev., together with text relative to same, as presented on pages 241 and 242 in Vol. 34 of the 1933 Proceedings, be published in the Manual.

The President:—Is there any discussion? All those in favor will say "aye"; contrary. It is carried.

Mr. D. C. Teal:—I move that Form 1303 appearing on page 957 of the 1929 Manual be withdrawn.

The President:—All those in favor of this motion say "aye"; contrary. It is carried.

Chairman C. C. Haire:—The next subject comes under the general heading of Valuation. We have had with us for a long time the subject that appears under Appendix H, Methods and forms for gathering the data for keeping up to date the valuation and other records of the property of railways. A report has usually been brought in each year attempting to record the many changes taking place because of Federal regulations, particularly changes on account of Valuation Order No. 3 and its various supplements.

The report will now be presented by Mr. Leete, the Chairman of the Sub-Committee, and is shown on page 617 of Bulletin 362.

Mr. P. R. Leete (New Haven):—As Mr. Haire said, the report of this Sub-Committee (E-1) will be found on page 617 of Bulletin 362.

During the past year there has been one change of importance, and that was the amendment to the Transportation Act. In order that you may draw your own conclusions as to what effect that will have upon our work, the paragraph of the original Act and the Act as amended have been printed here in parallel columns. About the only thing that I want to say is that we think there has been a feeling abroad by those perhaps not too well informed that the elimination of recapture has virtually cut the heart out of the valuation requirements. We feel that that is not so, except as to those carriers that were actually subject to recapture and had to defend themselves before the Commission. As to other carriers, the requirements are substantially as they were before.

As this matter is so closely tied in with the Depreciation Order and the proposed revision of the classification of accounts, there is very little progress that the Committee can make in the way of any definite recommendations until those matters are settled. The report is therefore submitted as information with the expectation that the subject will be continued.

The President:—The report will be so received.

Mr. Edwin F. Wendt (Consulting Engineer):—This subject of valuation has been under discussion at every convention beginning with the year 1913. At that time you will remember there was a popular misconception regarding the capitalization of the railroads of this country. Congress passed the Valuation Act. The Committee on Records and Accounts immediately began its consideration of what should be done to assemble the necessary records which were needed as a basis of an opinion as to the question of the capitalization of the railroads.

I think every member of this Committee has had a part in the work of the collection of these fundamental records, copies of which are to be found in the offices of the railroads.

Mr. Leete referred to a change in that part of the Valuation Act which relates to the correction of the valuations from time to time. I have only one thing to say regarding that. I hope this Committee will succeed in securing some simplification in the requirements of Valuation Order No. 3. It is my opinion that that order should be entirely rewritten. If that cannot be accomplished at this particular time, I think it should be something to look forward to, because Valuation Order No. 3 is now in some five, six or seven different parts. It was written by many different people, and, as I see it, now is the time to bring about a great simplification in the requirements with reference to the collection of permanent data.

The misconception respecting the capitalization of the railroads which was in the minds of many people previous to 1913 continued for many years. This misconception was not only on the part of men who were prominent in politics; it also existed in the minds of some very prominent people who took great interest in civic work. I think that we made a great advance, Mr. Chairman, in the matter of public sentiment in the last twenty years respecting this particular subject.

Last May, when Congress had under consideration the Emergency Transportation Act of 1933, Mr. Eastman appeared before the House Committee on Interstate and Foreign Commerce and before the Senate Committee on Interstate Commerce and stated freely and frankly that the railroads were not overcapitalized. As I sat and heard Mr. Eastman make this statement, I said to myself, "Certainly that marks an epoch in the history of the discussion of this matter of the capitalization of one of the greatest industries of our country."

Subsequently, on January 20, 1934, Mr. Eastman sent to Congress the first part of the report which he was required to make, and in that first chapter he made a significant statement which I think should go into the records of this Association. Mr. Eastman stated (and this is all to be found in his first report):

"Contrary to much popular impression, the railroads are not in the aggregate overcapitalized, in the sense that the par value of outstanding securities exceeds the money invested in the properties. The Bureau of Valuation of the Interstate Commerce Commission has estimated that the original cost of railroad carrier property, other than land, as it existed on December 31, 1932, plus land valued as of June 1, 1933, and plus allowances for working capital, was in the neighborhood of \$26,232,000,000. Original cost of lands is not known, but it was probably materially less than the value as of June 1, 1933. Making all due allowance for this fact, however, the original cost of railroad carrier property would not fall below \$24,000,000,000. On December 31, 1932, the total railroad capital actually outstanding was \$23,573,556,588, made up of \$10,226,070,233 in stock and \$13,347,486,355 in funded debt. Allowing for intercorporate holdings, the net capitalization outstanding in the hands of the public was \$19,489,062,256, made up of \$7,150,374,952 in stock and \$12,338,687,304 in bonds.

"While there was much inflation of the original capitalization of many railroads, this has since been offset, in the aggregate, by two principal factors: (1) Much investment of surplus earnings in carrier property by the more prosperous railroads, and (2) the scaling down of original capitalization through reorganizations."

That is the statement of Mr. Eastman to the Congress of the United States, and it seems to me that it effectively disposes of the idea which prevailed twenty years ago that the railroads were overcapitalized. The fact is that the railroads are undercapitalized. These figures indicate that, and I might go farther and give additional figures which would prove this undercapitalization.

The Chairman of the Sub-Committee made the statement that many people thought that there would be no further need for valuation work after the change that was made by Congress in the Act last June. I endorse what the Committee said regarding that matter. In my opinion, the fundamental data which has been collected and which is on

file in the offices of the railroads will be of as much use in the future as it ever has been in the past and may be even more useful.

It is interesting to know that the Securities Act of 1933, which does not apply to steam railroads, requires all corporations in this country to have their securities passed upon by the Federal Trade Commission. The Securities Act of 1933 is so severe in its requirements that any Engineer who prepares a report on any corporation engaged in common carrier service, and fails to include a material fact or makes a misstatement of a fact is subject to civil liability; that is, he is subject to being sued at any time within ten years after the time he files his report. If he deliberately makes a misstatement in one of his reports he may be sent to jail for a number of years. The question of valuation is now important in connection with other corporate properties by reason of the Securities Act of 1933.

There has been in progress in Washington, D. C., during the past six months a joint conference on appraisal practices. I bring that to the attention of the Committee. The conference is voluntary. It is composed of Engineers, architects, real estate experts, life insurance representatives, bankers and appraisers.

This conference has under consideration the question of the essentials of appraisal reports, and the reason for the conference is the new practice which is prescribed by the Securities Act of 1933.

I rise to commend the Committee for the excellent work which it has done (Applause).

Chairman C. C. Haire: The Committee is very glad, as always, to hear from Mr. Wendt, who was formerly Chairman of this Committee and served on it for a good many years. His advice is always helpful.

The next subject to be presented by the Committee is Methods Used in Recapture Proceedings, Appendix I, page 618. Mr. Silliman, Chairman of the Sub-Committee, is not present. I will briefly call attention to the report shown.

Mr. Silliman has been acting as a sort of reporter for this Committee. Each year he has recorded what has taken place in the recapture field, and now that recapture has passed out of existence, the report as shown is merely to close the assignment. It is offered as information.

The President:—It will be so received.

Chairman C. C. Haire:—Under the next group of subjects, the first one is Appendix J, Developments under I.C.C. Order No. 15100. The subject is closely allied to the one on revision of the accounting classifications, but the revision of accounting classification subject is not reported this year as there have been no developments. However, there has been an important development in connection with the depreciation subject. Mr. Hande, Chairman of the Sub-Committee, will call it to your attention.

Mr. J. H. Hande (Baltimore & Ohio):—Since the publication of the very brief report on page 618 of this Bulletin, there has come to hand the Commission's order of February 5 in which the depreciation requirements with respect to equipment have been made effective, calling for the establishment of rates on or before September 1, 1934, and for the inauguration of depreciation-accounting under the Order on January 1, 1935. Postponement for one more year with respect to road has been granted.

This Sub-Committee is in a peculiar position in that it is not in position to report on its assignment until there is an official issue of the classification and until the provisions in Order No. 15100 are recognized by suitable amendments to bring it in line with the pending classification. So we can do nothing further until those two orders are made final.

It may also be called to your attention that the entire matter of negotiation with the Commission with respect to the classification and Order lies in the hands of the Rail-

way Accounting Officers' Association, and we are estopped from making any reports until they have concluded their arrangement with the Commission. These brief developments are offered as information.

The President:—They will be so received.

Chairman C. C. Haire:—The concluding report of the Committee is methods for avoiding duplication of effort and for simplifying and coordinating work under the requirements of the I.C.C. This subject has been carried along for a number of years. We call attention to the fact that we are alive to the need of simplifying and working out a procedure which causes the least expense to the carriers.

The report as shown on page 619, Appendix K, is a record of what has transpired. However, there is a small correction to be made in this report. I will ask Mr. Knowles to call it to your attention.

Mr. C. A. Knowles (Chesapeake & Ohio):—Since the writing of the report to which Mr. Haire has referred, certain developments have taken place. A number of Engineers, among whom are members of Committee XI of your Association, have been assisting the Committee on Valuation Accounting of the Railway Accounting Officers' Association in the preparation of certain reports illustrative of the minimum requirements of the provisions of Valuation Order No. 3 of the I.C.C. It is understood that these illustrative reports, when completed, will be circulated by the Railway Accounting Officers' Association among the carriers interested. The members of Committee XI who have been aiding in this work have not, however, been assisting as representatives of Committee XI.

Chairman C. C. Haire:—That concludes the report of Committee XI.

The President:—This Committee has had in the past and will have in the future assignments that are of great importance to the railroads. Their function is to keep the Association informed of these developments. The Committee is now excused with the thanks of the Association (Applause).

## DISCUSSION ON ROADWAY

(For Report, see pp. 347-402)

Mr. Geo. S. Fanning (Erie):—The Roadway Committee's report will be found on page 347 of Bulletin 360. We had nine subjects assigned and are offering reports on five of them. On the first subject, Revision of Manual, we have nothing to report.

The second subject is Methods of Roadbed Drainage. You will find the report on page 348. This will be offered by Mr. H. M. Swope, of the Santa Fe.

Mr. H. M. Swope (Santa Fe):—This is the fourth year of this Committee's existence. Consideration of this subject has been continued in accordance with the outline adopted in 1931. The subject-matter developed by this Committee during the past three years has been adopted for publication in the Manual and is to be found in Proceedings, Vol. 32, Vol. 33 and Vol. 34. The following report concludes the study of this subject as outlined, and that portion of the report beginning with (C) Maintenance, page 348, to Recommendations on page 354 is recommended by the Committee for publication in the Manual. I so move.

The President:—It has been moved and seconded that the report as published, pages 348 to 354, be adopted and printed in the Manual. The motion is now before you for discussion. The Chairman desires to offer these by general subjects for discussion and amendment.

Mr. H. M. Swope:—(C) Maintenance; Maintenance of Ditches; Causes.

Mr. J. E. Willoughby (Atlantic Coast Line):—I think it might be of benefit if the Committee would give us some idea as to what they consider excessive grades for ditches and also insufficient grades for ditches.

Mr. H. M. Swope:—That has already been included in previous reports which have been adopted and are in the Manual.

Mr. J. E. Willoughby:—The Committee says: "Excessive grade tends to such rapid flow of water as to scour the bottom," etc. Some reference ought to be made as to what the Committee considers an excessive grade, by means of reference to other reports, if the information be contained in some other report.

Mr. H. M. Swope:—The first report of this Committee which is included in the revisions and additions to the 1929 Manual I believe includes what you have in mind. Of course, in the publication in the Manual this material will all be together in order, and this merely is a part of the report.

Mr. J. E. Willoughby:—I should think the Committee might make some references by note as to where the excessive grades and insufficient grades may be defined.

Mr. H. M. Swope:—We will take care of that.

Maintenance—1. Shallow Cuts, 2. Deep Cuts.

Under Deep Cuts I have received a written discussion from Mr. E. E. R. Tratman, which I will read: "In reference to the drainage of deep cuts, page 349, apparently the 'auxiliary track' mentioned is not of standard gage but is to be the narrow-gage equipment generally termed 'industrial' or 'portable' track. It may be well to modify the wording to: 'Industrial track of small gage, with small cars, may be used,' " etc.

It follows that where this method can be employed, it usually would be necessary to use the narrow gage. However, this is not always true, and I do not believe it should be specified in the Manual for that reason. This written discussion follows:

"During a trip to England last summer I noted numerous cases where deep cuts had drains of rough stone paving with squared blocks, laid up the slopes. The width would be four or five feet and between each pair of drains would be a similar longitudinal drain, not horizontal, but inclined as a flat V, with its apex midway between the two drains up the slope."

The drains in deep cuts which Mr. Tratman mentioned are to drain the slopes of wet cuts and is offered by him as information.

Ditching Machines. Maintenance of Drains. Pipe Drains: General, Inspection, Markers, Outlet ditch, Outlet pipes, Overflow, Flushing, Vegetation, Failure.

French or Rock Drains: Outlets, Outlet ditches, Silting.

Special Problems of Maintenance. Soft Spots and Water Pockets: Occurrence, Importance, Treatment. Slides: Definition, General.

That concludes the report by headings.

The President:—Is there any discussion on this motion? The motion is on the adoption of the subject-matter on Roadbed Drainage, pages 349 to 354. All those in favor will say "aye"; contrary. It is carried and so ordered.

Mr. H. M. Swope:—In order that existing material in the Manual pertaining to Roadbed Drainage be made to harmonize with this Committee's report, it is the recommendation of the Committee that the following changes be made in the 1929 Manual:

Page 23. Remove definition of slide.

Page 25. Under "drainage" add definition: French Drain—Underground passages for water through the interstices among stone placed loosely in a trench.

Make the following revision to "Specifications for the Formation of the Roadway", pp. 28 to 36, inclusive: Page 31. Add the following to Section 30, "Intercepting Ditches": "The material excavated from the ditch shall be deposited on the side of the

ditch towards the cut, unless otherwise directed. The slope of the waste bank from its summit towards the ditch shall be as long as feasible. In crossing light depressions in hillsides, when directed, levees shall be constructed and the depression filled above the levee so as to bring its surface up to the grade of the ditch. The top surface of this fill shall be of puddled clay.

"Intercepting ditches, when ordered, shall be made on the upper side of the fills where the ground slopes towards the embankment. The cross-sections and locations of such ditches shall be designated. Unless otherwise ordered, the waste dirt shall be placed so as to provide a slope from the toe of embankment to the ditch. If required, they shall be excavated in advance of the construction of the embankment."

Pages 31 and 32. Replace all of Section 32, Subdrains, with the following:

"Pipe subdrains shall be constructed of the material and size and in the location shown on the plans, or as directed, and to the depth and grade established for them. The cross-section of the trenches shall conform with the plans, and the trench shall be excavated and the pipe laid to true line and grade. Sufficient cribbing or shoring must be used to prevent caving of the trench excavations. All trenches shall be backfilled with an approved permeable material, kept free from dirt, dust and other foreign material. The finished section of the backfill shall conform with the plans."

Page 33. Add the following to Section 40, "Finishing Subgrade": "It must be maintained in this condition until the ballast is placed (or until accepted). Any back-filling necessary to make a smooth surface shall be made of the same material as exists in the roadbed.

"Where roadbed, in either cuts or fills, is composed of a more or less clay material, all construction tracks shall be removed after the work has been brought to grade and the subgrade rolled with a road roller weighing about 10 tons and thus brought to proper crown and surface."

Page 40. Remove all material under "Slides", Articles 1 to 12, inclusive.

Page 41. Replace Fig. 2 with two plates illustrating roadbed drainage.

Page 46. Remove "Means for Prevention or Cure of Water Pockets in Roadbed", Articles 1 to 6, inclusive.

Page 50. Remove all material under "Soft Spots".

Pages 50, 51 and 52. Remove all material under "Ditching".

I move that these changes in the 1929 Manual be adopted.

The President:—Is there any discussion? All those in favor of adopting these recommended changes say "aye"; contrary. It is carried and so ordered.

Chairman Geo. S. Fanning:—Our third subject is on the service life and specifications for railway fence wire. Our Sub-Committee has been cooperating with the American Society for Testing Materials and hopes to have a final report during the coming year.

On the fourth subject, practice of jacking culvert pipe, you will find the report on page 355. This will be presented by Mr. O. H. Wainscott, of the Illinois Central, in the absence of the Chairman, Mr. Noble.

Mr. O. H. Wainscott (Illinois Central):—In making this report the Committee had in mind providing the source of information for those unfamiliar with work of this kind, from which they could secure sufficient data to prepare an estimate of the cost and also enable them to select some suitable method to carry out the work. It is the recommendation of the Committee that this report be received as information and the subject be discontinued.

The President:—Is there any discussion on this subject? It occurs to the Chair that this is subject-matter for the Manual, and I may ask the Committee why they are not recommending it for the Manual.

Chairman Geo. S. Fanning:—This subject is rather new, and we would like to have

our recommendations tried out for a few years, and then we will ask that the subject be reassigned and then put it in shape for the Manual.

The President:—Unless there is objection, we will handle it in that way.

Chairman Geo. S. Fanning:—Our fifth subject is Bearing Power and Other Physical Properties of Soils, including Effect Upon Roadbed. The report will be found on page 364. It will be offered by Mr. E. R. Lewis, of the Michigan Central, in the absence of Mr. Legro.

Mr. E. R. Lewis (Michigan Central):—The information contained in this report is preliminary to a presentation of principles which the Sub-Committee is engaged in materializing in its study, as well as data concerning developments, particularly of the past few years. It includes soil terminology in which a more complete description of terms is given than may be convenient to include in the body of future reports using these terms.

The report is offered as information.

The President:—Is there any discussion on this report? I would like to call attention to the fact that this subject is one of the subjects selected by the General Committee of the Engineering Division for report. It is considered a very important subject, and the Committee has made a start on it. I am sure they will be glad to have any suggestions that the membership may have to offer. It will be received as information.

Chairman Geo. S. Fanning:—Our sixth subject is on Methods of Protecting Against Drifting Snow and Opening Snow Blockades. The report will be found on page 370. It will be offered by the Chairman of the Sub-Committee, Mr. F. W. Hillman.

Mr. F. W. Hillman (Chicago & Northwestern):—Last year this Committee presented a report on "Methods of Protecting Against Drifting Snow and of Removal of Snow on the Line and in Yards and Terminals" as information, with a recommendation that this subject be reassigned. In the reassignment there was a modification made of the subject as indicated. The Committee collaborated with Committee XXVII—Maintenance of Way Work Equipment, as instructed. The report follows on page 370.

There has been no attempt whatever to give any specific recommendations because of the fickleness of snowstorms, and only general rules have been suggested.

The report is divided into two sub-divisions as suggested by the title, first, Protection Against Drifting Snow. Mention is made of the necessity of removing obstructions, and also of placing obstructions such as the fixed and portable fences. It has been suggested that a diagram or sketch indicating the slat and wire type fence be included in the Manual. This was discussed at length in the Committee, and it was decided that as this type of fence is so commonly known we would not burden the Manual with another sketch.

The next sub-division is Opening Snow Blockades. This is divided into the general statements—the necessity of keeping the line open, and the precautions that should be taken by the general officers in keeping in touch with the men. Then there are suggestions for handling blockades on the line and in yards and terminals. There is an error under "In Yards and Terminals" in the third line of the last paragraph on 375. The word "of" should be crossed out. This report is submitted for publication in the Manual, and I so move.

The President:—It has been moved and seconded that this report be adopted as recommended practice and included in the Manual. That motion is now before you for discussion. I will ask the Chairman to give you the opportunity to discuss each part of the report by reading the captions.

Mr. F. W. Hillman:—Protection Against Drifting Snow.

Mr. J. E. Willoughby (Atlantic Coast Line):—In the heading "Permanent Snow Fence, Open Boarding," there is not designated the character of material that that fence

be built of in order to make it permanent. What is meant, I take it, is a fence in a fixed location.

Mr. F. W. Hillman:—What paragraph?

Mr. J. E. Willoughby:—Page 372.

Mr. F. W. Hillman:—That was accepted in the Manual several years ago, and we have not seen fit to change it.

Mr. J. E. Willoughby:—Does the Committee maintain that a snow fence built of ordinary pine boards is a permanent fence?

Mr. F. W. Hillman:—I think anybody who would so consider it would be foolish. Probably the word "permanent" is wrong and it should be "fixed," but that has been adopted in the past. It seems to have served the purpose, and to indicate what we mean.

The President:—I suggest that the Committee on Manual consider that item and edit it properly.

Mr. F. W. Hillman:—Opening Snow Blockades: General; On Line; In Yards and Terminals.

The President:—Is there any discussion on this subject? Are you ready for the question? The question is on the adoption of the report as printed, pages 370 to 376, inclusive, as recommended practice and for inclusion in the Manual. All those in favor will say "aye"; contrary. It is carried and so ordered.

Mr. E. E. R. Tratman (Civil Engineer):—In regard to snow fencing, since the slat-and-wire type is stated, on page 371, to be replacing other portable types mentioned, it would be useful to illustrate this as well as the other types.

Chairman Geo. S. Fanning:—The seventh subject is on Specifications for Galvanizing Metal Culvert Pipe. Progress is reported on this subject with a recommendation that the subject be broadened to include a complete review of the Specifications for Corrugated Metal Culvert Pipe. This is being done by the 1934 Committee.

Our eighth subject is service life of culverts. This is a new subject this year. The Committee reports progress in organizing its work.

Our final subject is on methods of protection against drifting sand. This will be found on page 376 and will be offered by Mr. C. W. Baldrige, the Chairman of the Sub-Committee.

Mr. C. W. Baldrige (Santa Fe):—The subject "Methods of protecting against drifting sand," is one problem with which many railways do not have to contend, but which, on many other railways, as well as on many highways, irrigation ditches, sea coasts, and other places, is a very serious problem.

But little effort seems to have been made in the past to secure and make available information regarding protection against drifting sand. Seemingly, most people have regarded the problems resulting from the drifting of sand and dirt to be the same as those arising from drifting snow, but this is far from the case in one important particular, that being that protection against drifting snow must take care of the drifted material for one winter only, the summertime removing the drift entirely, while a drift of sand once made must be removed by artificial means or be lived with always.

The responses to the requests for information made by members of the Committee were very gratifying, and they show a very wide interest in the subject. In some cases, the responses have carried practically identical information. Therefore, in such cases, while all the papers received are much appreciated, but one is published. Some excellent reports in which some new features were presented, were received after the Committee's report had been sent to the Secretary for printing. Such reports are in the hands of the Committee and will be handled in the coming year's work.

To all those who have sent information to us, the Committee extend their thanks.

The matter in this report from pages 376 to 401 is offered as information. The conclusions beginning on page 401, and reading as follows, are offered for inclusion in the Manual:

"1. Protection against drifting sand, as is the case with snow, should begin with the construction of the road, be it railway or highway.

"2. Wherever drifting or blowing sand is probable, the roadway should be constructed above the natural ground level where possible and all obstructions which might cause the deposit of sand should be removed and the embankments faced with clay, oiled sand or some other substance which will provide a smooth surface, thus allowing the blowing sand to keep on moving, thereby avoiding drifts.

"3. If cuts cannot be avoided, they should be constructed with flat, smooth slopes and the drifting of the sand controlled by the construction of open-bottom wind chute fences as shown on page 400 of Volume 35 of the Proceedings.

"4. On existing lines the same remedies should be used where applicable.

"5. Wherever sand drifts occur between the rails of a railroad track, the ballast should be cleared out to a half skeletonized condition, to permit the wind to pass under the rails, thus clearing the sand away.

"6. Where the source of the blowing sand can be controlled by the planting of vegetation, such treatment may be the most economical method of protection, and should be considered.

"7. Where moving sand dunes exist they sometimes may be dissipated by the scattering of gravel or small stones over the face of the windward slope.

"8. Where trouble is experienced from sand blowing out of embankments, thus undermining the track, or from its blowing out of the sides of cuts causing slides or other damage, the proper remedy is usually the covering of such surfaces with a layer of clay or other stable material.

"The Committee recommends that the above conclusions be adopted for inclusion in the Manual." I so move.

(The motion was regularly seconded.)

The President:—It has been moved and seconded to include these conclusions in the Manual as recommended practice. Is there any discussion? All those in favor will vote "aye"; contrary. It is carried and so ordered.

Chairman Geo. S. Fanning:—That concludes the report of the Roadway Committee.

The President:—As usual, this Committee has presented a very valuable report. They will now be excused with our thanks (Applause).

## DISCUSSION ON CLEARANCES

(For Report, see page 675)

Mr. A. R. Wilson (Pennsylvania):—This report is found in Bulletin 363, page 675. The diagram in the report has been before you for a year, it being presented last year. This diagram representing the outline of the proposed box car was prepared by the Mechanical Division of the American Railway Association. That Division and several other Divisions have held several conferences, and, under the direction of the A.R.A. a questionnaire was issued to all members and associate members of the American Railway Association.

In studying the questionnaire and compiling the results it was found that a car built to these dimensions can be operated over 97½ per cent in interchange service of the railroads in this country and Canada.

The questionnaire also developed that there were a number of pieces of equipment exceeding this outline, nearly 11,000 locomotives exceeding this outline, however, locomotives are not used in interchange service. This diagram will continue the series that

this Committee presents from time to time supplementing Fig. 1, 2, 3, 4 and 5 which have been adopted by this Association and appearing in other Bulletins.

A suggestion reaching the Committee too late to have a committee meeting suggests to us that we change somewhat our recommendation, deleting all information or reference to a proposed A.R.A. box car, our report which is presented for adoption in the Manual reading, "that the limiting equipment diagram for interchange service, Fig. 6, be approved and printed in the Manual." This change in the title of the diagram is consistent with the assignment to this Committee.

I move that this diagram be approved as the limiting equipment diagram for interchange service.

The President:—You have heard the motion, gentlemen. Is there any discussion? All those in favor say "aye"; contrary. It is carried.

Chairman A. R. Wilson:—This concludes our report, Mr. President.

The President:—The information presented by this Committee is timely and valuable. They are now dismissed with the thanks of the Association (Applause).

## DISCUSSION ON BALLAST

(For Report, see pp. 663-670)

Mr. A. D. Kennedy (Santa Fe):—The report of this Committee is given on pages 663 to 670 of Bulletin 362.

The first assignment is Revision of Manual. The Committee has a few recommendations to make in this particular but it will be handled in connection with the report of the Sub-Committee on Assignment No. 6, Appendix D.

The next assignment is Specifications for Prepared Gravel Ballast, Including Best Method of Testing for Hardness, Abrasion and Resistance to Weathering. The report will be submitted by Prof. Foster, in the absence of the Chairman of the Sub-Committee.

Prof. W. L. Foster (Iowa State College):—The Committee has no new information to offer at this time. Last year the work consisted of correlating the data previously secured. However, sufficient correlation has not been found to exist between the laboratory test and field observation, and the Committee feels that more information must be collected and analyzed before definite recommendations can be made. It is recommended, therefore, that the subject be continued and that the Association have patience until economic conditions improve.

The President:—The subject will be continued.

Mr. A. D. Kennedy:—The next assignment to the Committee is Specifications for Stone Ballast, Including Best Method of Testing Resistance to Weathering (Appendix B). The report will be presented by Mr. Podmore, Chairman of the Sub-Committee.

Mr. J. M. Podmore (New York Central):—Last year your Committee submitted as information an alternate method for making an abrasion test on crushed stone as produced for ballast, known as the Modified Abrasion Test. Before recommending the adoption of this test, it seems desirable to await developments from a series of tests which largely have been completed on still another modified form of abrasion test, making use of the so-called Los Angeles Rattler. Your Committee recommends that the test for abrasion be given further study.

Last year your Committee recommended that the section dealing with cementing value be removed from the Specifications for Ballast. However, by instructions from the convention the subject of cementing value has been given further study. During the past year a questionnaire was sent out to railroads. Answers were received from 58 railroads, six of which advised that the cementing value tests were used by those roads. The

test requirements specified by the six roads using the cementing value test varied all the way from 1 lb. to 450 lb. per sq. in.

In view of the wide variation in specifications of the six roads using the cementing value test, it is evident that an inconsistency exists. Because of this inconsistency it seems desirable to initiate a cooperative series of tests which will shed light on this entire matter of cementing value of rock for use as railroad ballast.

Your Committee is taking steps to initiate a cooperative series of cementing value tests with objectives as already indicated, with the hope of obtaining information of practical value for use in Specifications for Ballast.

The above report is recommended as information and the subject be continued.

The President:—The Committee would like some discussion on this specification. The specification will be received as information and printed in the Proceedings.

Mr. A. D. Kennedy:—The next assignment is Comparative Costs of Maintaining Track on Various Kinds of Ballast. The Sub-Committee has rendered a report which is shown under Appendix C on page 667. This is to be considered as a progress report, and they wish to advise that an earnest effort will be made to have a specific test installed on one or more railroads to bring out some dependable data on this subject. The Committee reports progress and wishes the subject to be continued.

The President:—Is there any discussion on this subject?

Mr. A. D. Kennedy:—I would say, however, the Committee would sincerely like to have some suggestions on this subject.

The President:—The subject will be continued.

Mr. A. D. Kennedy:—The next subject of the Committee is Effects of Different Kinds of Ballast on Life of Ties, on Life of Rail and Upon Rail Failures, particularly as between gravel and crushed stone ballast. The Sub-Committee assigned to this subject reports progress, and we would like to have the subject continued for further study.

The President:—It will be so received.

Mr. A. D. Kennedy:—The next assignment of the Committee is to determine proper depth and kind of sub-ballast. This subject has been before the convention for a number of years, and the report of the Sub-Committee is shown in Appendix D on page 668.

The report, in a measure, is fashioned after suggestions made on the floor of the convention last year, in that the first portion of the report is devoted to a historical review of what has gone before on this subject, and this historical review is concluded by quoting what is now included in the Manual under the heading of "Proper Depth of Ballast."

The Sub-Committee has spent considerable time in studying this subject, but we regret that we can only bring a negative report to this extent, and this is embodied in the report in Appendix D on page 669:

"The thickness or proper depth of sub-ballast to use depends upon sundry conditions and variables. Experienced Engineers, after acquainting themselves with all the conditions to be encountered, should be able to approximate the proper depth to use."

In our research we were unable to support any specific depth of sub-ballast, and the Sub-Committee continues as follows:

"For lack of definite information regarding the many existing and ever-changing conditions particular to each location, your Committee feels this Association cannot defend, except by opinion, a ballast section of any specific dimensions. However, there is information contained in the Proceedings of the Association, reference to which is given in this report, which, if intelligently interpreted, would be a guide in determining both the proper depth of ballast and sub-ballast to use in any particular location."

That is the finding of the Sub-Committee.

The President:—Is there any discussion on that part of the Committee's report?

Mr. J. B. Jenkins (Baltimore & Ohio):—The Committee makes the statement: "After years of service, the sub-ballast of an original ballast section loses its identity as such. It becomes so mixed with the subgrade that a distinction is impossible."

In connection with the valuation inventory of the railroads, trenches were dug through the old ballast about every thousand feet, and it was the exception rather than the rule to fail to find a very marked line between the ballast and the subgrade. In only a small minority of locations did the ballast or sub-ballast get mixed with the subgrade.

Mr. Frank Ringer (Missouri-Kansas-Texas):—I would like to support what Mr. Jenkins just said. Some years ago we had an occasion to make quite a series of tests along that very line. It was the marked exception rather than the rule where we were not able to establish a clear line between the sub-ballast and the original roadbed material.

Mr. J. C. Irwin (Boston & Albany):—I want to endorse this idea that the conditions are not always as stated in this report, and it is too general to be taken as a common situation.

On our New England railroads, particularly, where we have a good subgrade, wherever we cut out for a bridge or culvert and get an original cross-section, we get a beautiful definition between the sub-ballast and the top ballast without any settling of the sub-ballast into the subgrade at all. On the other hand, in clay formations, particularly in soft clay fills, the ballast does work down into it, but I think we have to recognize the fact that it depends entirely upon local conditions. I have seen some sections which I might say are seventy or eighty years old where you can find the demarcation between the various kinds of ballast very clearly.

Mr. C. W. Baldridge (Santa Fe):—I believe the statement this Committee has made is that the depth of ballast as now recommended in the Manual seems to be based entirely on opinion.

A number of years ago the Special Committee on Stresses in Track gave us a report in which they gave charts showing the stresses and pressures developed in ballast in roadbeds. It was quite an extended report and a very excellent study.

The Ballast Committee, following that report, used the information given in that report of the Stresses in Track Committee, to find the required depth of ballast. Unless this Committee have something better to offer than what is in the Manual I would oppose making any change at this time.

The President:—The Chair was just about to mention that the report of Dr. Talbot on Stresses in Track, as Mr. Baldridge has pointed out, contains some very valuable information on which the Committee can substantiate their conclusions. Dr. Talbot is present, and I would like to have him say something on this subject.

Dr. A. N. Talbot (University of Illinois):—I am not generally critical, but I may say that I am disappointed in the Committee's report on the function and value of ballast. It is more in what the report does not say than in what it gives. The statement for insertion in the Manual says: "Depth of ballast should exceed the minimum required to uniformly distribute superimposed loads to the subgrade without causing its deformation."

Of course, that would be accepted as a generality—but how much should it exceed the depths given in the standard ballast sections in order to cover the unevenness and variations that may occur along the railroad in the way of drainage and in variety of materials below the ballast? What kind of subgrade does this refer to? Is it one that is always drained and is solid and substantial, as was referred to by someone just now, or is it thought that the ballast serves principally to drain and take the water down to material just below, which with this water may become wet and mucky and easily de-

pressed by uneven pressures? Is there any factor of safety provided for the unknown and occasional conditions of the subgrade? What variations may be expected?

In the Second Report on Stresses in Track it is shown that instead of the distribution of pressure away from the tie width beginning at the bottom of the tie the lines of pressure first incline inwardly and not outwardly as is usually assumed, so that at a distance of 5 or 6 in. below the bottom of the tie the concentration of pressure is materially greater than it is immediately under the tie. Below this level the lines of pressure diverge so that at a distance of 10 or 12 in. below the bottom of the tie, the distribution of the pressure is not particularly different in intensity from that existing at the bottom of the tie. Below this level the lines of pressure continue to diverge and for the ordinary tie spacing at 18 or 20 in. down the distribution longitudinally of the track is fairly even, provided the material below is uniform and will support the load coming on it under all conditions whether wet or dry. The foregoing is a necessary condition of granular material, which I think we must accept.

In addition to drainage, the upper part of the ballast then acts as a sort of mechanism to transmit the pressure down to where it will spread out further (see Fig. 95 to 100, Second Progress Report of the Committee on Stresses in Railroad Track, Proceedings A.R.E.A., Vol. 21, 1920). Doubtless, much of this mixing of materials which has been spoken of in the discussion occurs by reason of an inadequate depth of ballast being applied at the beginning, not sufficient depth to cause the pressures to spread out so that the lines of pressure between the ties will meet within the depth of the ballast. The concentration of pressure under a tie should not be such as to permit the ballast to be forced down into the material below, especially when this lower material is wet and cannot support high concentrated loads. The larger particles of ballast may be forced down into the subgrade, but this is much more likely to occur with shallow ballast than with an adequate depth.

The question may well be raised whether 12 in. of top ballast is sufficient. The question may also be raised whether the methods ordinarily used of adding a few inches of ballast at a time, before a sufficient depth is applied, are effective in realizing the best value of ballast.

What is there in the report to give an idea of when the mixture of ballast and dirt, referred to in the discussion, is sub-ballast and when is it merely subgrade? Is there any thing to indicate what is to be called the top-ballast and what the sub-ballast?

In the diagram in the Manual the depth of 12 in. of top-ballast and 12 in. of sub-ballast has no definition, nothing to tell what is meant by these terms. In the diagram for Class B Track, the minimum depth is given as 9 in. under the ties, and this is recommended for the firmest, most substantial and well-drained subgrades. Should there be given a warning that this depth does not provide an even distribution of loading on the subgrade along the track? What is to be done for less substantial subgrade?

In the diagram for Class C Track there is 6 in. of material; this will give some drainage of the ballast. This depth, however, does not give distribution of pressure—rather a concentration. Under traffic it may be expected to be easily forced down into the subgrade.

Would it not be well to give something on the function and value of ballast other than that of drainage? Cannot something be said on principles relating to the lateral and vertical distribution of pressure downward through ballast? What mixtures of gravel or broken stone with dirt can be called ballast? Will depths of ballast beyond those that may be expected to provide fairly uniform distribution over an excellent subgrade be desirable as a margin of safety against the variability of subgrade conditions from point to point along the track? Is it too much to ask if an attempt should not be made to prepare something that at least will give a clue to the advantages of deep

consolidated ballast (beyond the minimum depths) which can be used in evaluating the extra expenditure—the added stiffness and stability of the track structure and the decreased cost of maintenance?

Is the Committee on Ballast lukewarm on the value of ballast?

Mr. A. D. Kennedy:—I will say this, on behalf of the Committee, that the Committee has recognized in their discussions and in their conferences the objections that have been raised on the floor, but, nevertheless, after lengthy research we have been unable to get definite information that would enable us to make a definite recommendation as to proper depth.

The idea in making this report is to make it rather general so as to leave it to the opinion of the Engineer in charge. In this particular we have made particular reference to the history of the subject in the Association and called attention to matters that would help them in making a decision. In this particular we call attention to the discussions of the Committee on Stresses in Track.

I still feel that the Committee has complied with their present instructions, and I also feel sure that the Committee cannot go any further into this question unless an appropriation is made by the Association to install a special test. We have exhausted all our information in this particular. If any of the members either present or not present can give us any definite clew that we can follow, we will gladly accept it.

This question of the proper depth of ballast has been before the Association since 1907, and it is still unsolved. As I said before, we welcome any specific suggestions.

Mr. C. W. Baldrige:—The question has been before this convention longer than that, about thirty-five years, in fact. It was thrashed over very thoroughly a number of times. When the matter which is now in the Manual, recommending 12 in. of sub-ballast and 12 in. of top ballast was adopted, it was after a great deal of discussion and study. Unless this Committee can offer us something to put in the Manual, more than telling a man to use his judgment, we might as well leave it out. A man can use his judgment without a Manual. I believe that the Committee's recommendation of a substitute for what is now in the Manual should be rejected.

Mr. A. D. Kennedy:—I will say in reply to the last speaker that I do not for a moment wish to be contradictory to the general opinion, but I have made a survey of all the Proceedings of the Association since 1902 and I have failed to find where the Association or the Committee has been justified in making the recommendation that is now shown in the Manual.

For your information, under the heading "Proper Depth of Ballast" which is now shown in the 1929 Manual on page 102, it reads as follows:

"(1) On a roadbed material such as clay, loam, etc., subject to deformation by the application of live load, the proper depth of ballast under the tie to produce approximately uniform pressure on the roadbed, should be not less than the spacing center to center of the ties. For Class A Track, see Ballast Sections.

"(2) On material that approximates the character of good sub-ballast (which will not be deformed by the application of live load), the minimum depth of ballast under the bottom of the tie should be twelve (12) in.

"(3) These depths are required, under the conditions named, to support the track structure; to provide good initial drainage; to reduce upheaval by frost; to serve as a cushion for the track."

I am going to skip (4) and cite (5).

"(5) Until sufficient tests are made under normal traffic conditions, the proper depth of ballast under the tie must rest on opinion, based on experience and supported by such tests as are available, notably the test made by Director Schubert of the German Railways and the 'Altoona Test' made by the Pennsylvania Railroad."

So you see that paragraph (5) nullifies the previous recommendations that are contained in the Manual.

Mr. C. W. Baldrige:—I fail to agree with the gentleman that Section (5) nullifies what went before. The three paragraphs read, make a definite recommendation, and if those steps are not sufficient, then Paragraph (5) would control. Paragraph (5) is, in reality, going beyond the depths that are recommended and does not cancel any previous recommendations.

Mr. A. D. Kennedy:—That is purely a matter of opinion. The opinion of the Committee is to the effect that it does contradict paragraphs (1) and (2). Paragraph (3) reads, as I said before:

"These depths are required, under the conditions named, to support the track structure; to provide good initial drainage; to reduce upheaval by frost; to serve as a cushion for the track."

You will agree that paragraph (3) is covered by the definition of ballast previously quoted in the Manual. Paragraph (6) reads:

"Proper drainage of the subgrade is essential to success with any kind of ballast."

That is self-evident.

Mr. H. L. Ripley (New Haven):—What is now in the Manual was put into that Manual some twelve or fifteen years ago while Mr. Baldrige was a member of that Committee and, I think, while I was Chairman of that Committee.

I think it is going a little beyond a statement of fact when you say that it rests entirely on opinion, because the Altoona test made by the Pennsylvania Railroad was quite an extensive, if not exhaustive, test, and the studies made in Germany also were made on what was considered a scientific basis and were very helpful to the Committee. There were other tests made at the time. I want to support what Mr. Baldrige has just said, that those depths, and particularly that language used; that, in order to support the track properly, the depth of ballast should not be less than the spacing center to center of ties, was not based merely on opinion, although opinion was sought, and very extensive opinions were expressed by those who were familiar, through long practice, with the actual experience of ballast.

The basis was the tests that had been made, supplemented by the opinions which we sought, and got, from experienced Maintenance Engineers at the time.

I also want to support what Mr. Baldrige said about paragraph (5); that it covered cases where it was found that the depth of ballast below the bottom of the tie, when tried or tried under similar conditions, was found to be insufficient. That is particularly true in some of the clay countries, and on some of the material which we have up in New England which goes by the colloquial name of "bull liver," a quaking mass, where experience has shown us who have had to deal with it that sometimes we have to go down three and four feet in order to get a proper depth of ballast under the tie, not perhaps to support it for the first day but so that it will not pump up through the ballast but will stay as ballast and not become an aggregate of earth and ballast, and, eventually, not materially better than the poor soil found below the ballast line.

Mr. John V. Neubert (New York Central):—I may be out of order, but I believe the idea is to withdraw that which is now in the Manual specifying the depth of ballast. Is that correct?

Mr. A. D. Kennedy:—Yes.

Mr. John V. Neubert:—I am objecting to that because I believe that in the railroad field today, with various kinds of ballast and traffic conditions, we should know what is known as the minimum depth. Irrespective of what you may think, I believe

your Committee is well qualified, from practical experience and knowledge, as to what they would recommend.

If you feel you should have some research in regard to making an investigation of what the proper depth of ballast should be, I think you should go back to the Board to help you obtain that information. The reason I am bringing that out is I believe the Board has appointed a special committee, and your Committee is represented on that special committee. The common expression is that a railroad track is as good as its ties. How are you going to support that tie unless you have some ballast? As brought out forcefully by Dr. Talbot, not only in one of his reports but in many of them, ballast is essential to the upkeep, and the proper upkeep of your railroad. I would be opposed to withdrawing that from the Manual. I think you fellows can handle it, and I know you can handle it.

The President:—I think we have been getting a little ahead of ourselves. In other words, we have got the cart before the horse. The intention of the Committee, as I understand it, is to substitute some matter for that already in the Manual. There has been no motion to do that.

If, in the light of this discussion, the Committee still feels they are warranted in substituting this matter for that in the Manual, I think the time is now appropriate for a motion to that effect.

Mr. A. D. Kennedy:—I will make the motion, and I am still of the opinion that what is now in the Manual is erroneous, regardless of what we are going to substitute for it, with due respect to the members of the committees which have gone before, the fact that the language used in paragraph (5) does nullify the previous paragraphs because it states: "Until sufficient tests are made under normal traffic conditions, the proper depth of ballast under the tie must rest on opinion."

In lieu of the six paragraphs under "Proper Depth of Ballast" your Committee recommends the following:

"(1) There is a relationship between several conditions, viz., rail section, ties, tie spacing, kind of ballast, speed, wheel loads, drainage, subsoil, kind of traffic, etc., and the depth of ballast. Depth of ballast should exceed the minimum required to uniformly distribute superimposed loads to the subgrade without causing its deformation. Available data does not support a definite specification with reference to required depth for general application under all conditions.

"(2) In new construction a combination of good sub-ballast and top ballast does, with few exceptions, produce better results than a superior material used for the full depth. The ratio of the one to the other and the total depth in the aggregate should be determined with due consideration given to local conditions, as outlined in paragraph 1."

Then we give a note: "In the absence of more specific data, the tests made by Director Schubert of the German Railways (Vol. 7, pages 104 to 127) and by the Pennsylvania Railroad (Vol. 13, pages 95 to 265), although not conducted under regular traffic conditions, are of great value as a guide in determining the depth of ballast required for any given section of track.

"Reference is also made to Vol. 12, Part 1. On page 341 are given some of the conditions on which depend the proper depth of ballast and in Appendix A, page 345, is given the depth of ballast used at that time by representative railroads."

I move that what I have quoted here be included in the Manual and what now appears under "Proper Depth of Ballast" in the Manual be withdrawn.

The President:—It has been moved and seconded to include this subject-matter in the Manual in lieu of the present subject-matter. Is there any further discussion on the subject?

Dr. A. N. Talbot (University of Illinois):—May I ask whether this motion implies also that the ballast sections shown on pages 103 and 104 of the Manual are to be retained without any modification, and why it is stated in the paragraph of the report following what has just been read that the sections do not admit of any modification? Does this refer to depth of ballast regardless of conditions?

Mr. A. D. Kennedy:—For the information of the last speaker, the captions on these sections are to be revised, and I will presently make a motion to that effect, that they will admit of modification.

Mr. Edwin F. Wendt (Consulting Engineer):—I would like to amend this motion by striking out all after the first word and substituting the following: That the subject be referred back to the Committee for further study in the light of the discussion from the floor today.

The President:—The question before the house is on the recommitment of the subject.

Mr. J. C. Irwin (Boston & Albany):—My thought is we are on the way to the solution of such problems as this through action already taken. To begin with, the chairmen of the committees have been asked during the year to give the Board any recommendations that they may have in regard to research or tests which may be necessary for them to solve their problems. I think that would be the first thing for this Committee to do in order to get more definite information.

Further than that, we have recently formed the Committee on Complete Roadway and Track Structure for the very purpose of bringing together the various elements of roadway and track and being able to solve problems which involve a combination of all elements. In that connection, the Roadway Committee is studying the bearing power of soils. It has a very distinct bearing on the depth of ballast and the relation between the sub-ballast and top ballast.

In that connection, I think the motion to refer back to the Committee is very suitable. It will be further investigated through that Committee in that way as well as being considered by the new Special Committee on Complete Roadway and Track Structure.

The President:—The question before the convention is on referring this matter back to the Committee. Is there any further discussion? Are you ready for the question? All those in favor will say "aye"; contrary "no." It is carried and so ordered. That motion therefore voids the original motion for adoption.

Mr. A. D. Kennedy:—The last subject of the Committee is Effect of Better and Deeper Ballast on the Cost of Lining and Surfacing. The Sub-Committee on this assignment reports progress.

That is the extent of the Committee's report.

The President:—This Committee has done considerable work in spite of the fact that the subject is being referred back to them. They are now dismissed with the thanks of the Association (Applause).

## DISCUSSION ON TRACK

(For Report, see pp. 923-955)

Mr. C. J. Geyer (Chesapeake & Ohio):—The report of the Committee on Track will be found in Bulletin 364. Your Committee reports this year on fifteen subjects.

Appendix A, Revision of Manual, begins on page 924. The first subject in the Revision of Manual is, that the material shown under the headings "Table of Dimensions for Tie Plates" and "Data for Designing Tie Plates", on page 251 of the 1929 Manual, be withdrawn.

I so move.

The President:—You have heard the motion. Is there any discussion? All those in favor will say "aye"; contrary. It is carried.

Chairman C. J. Geyer:—The second subject on Revision of Manual, the Committee proposes as recommended practice, that the design of cut track spikes, appearing in the Manual at page 254, be revised as follows:

The elimination of the dimensions which provide for optional lengths of spikes and in substitution therefor incorporation of dimensions providing for a single length of 5-½ in. between the throat and point for 9/16 in. spikes, and a single length of 6 in. for 5/8 in. spikes.

I move the approval of that.

The President:—Is there any discussion? Mr. Geyer might explain that the present spike shown in the Manual, I believe, is 5-½ to 6 in.

Chairman C. J. Geyer:—The present information on spikes in the Manual permits lengths of both 5-½ and 6 in. for both the 9/16 and the 5/8 in. track spikes. It is now simply proposed, for simplification, to furnish those two spikes in one length each only.

The President:—Is there any discussion on the subject? All those in favor of the motion will vote "aye"; contrary. It is carried.

Chairman C. J. Geyer:—The Committee recommends the withdrawal of track tool plans Nos. 1, 2, 3, 5, 6, 9, 11, 12, 13, 14, 15, 16, 18, and 19 adopted in 1930 and substitution of plans of like numberings herewith submitted.

I move that these new plans herewith submitted be adopted as recommended practice and printed in the Manual.

The President:—It has been moved and seconded to adopt the plans as printed, as I understand, from pages 936 to 947, inclusive.

Chairman C. J. Geyer:—That is right.

The President:—In order to give the members a chance to discuss and amend, I will ask the Chairman to call attention to each particular plan, and if anyone has anything to say they will please stand up and say it at that particular time.

Chairman C. J. Geyer:—Plan No. 1, Clay Pick, dated September, 1929, revised September, 1933.

Plan No. 2, Tamping Pick, dated September, 1929, revised September, 1933.

Plan No. 3, Spike Mauls, dated September, 1929, revised September, 1933.

There is no revision in Plan No. 4, which is the next one following.

Mr. R. P. Winton (Norfolk & Western):—No mention is made of Plan No. 4. I want to call attention to a note which says, "All wrench jaws shall be milled to exact dimensions shown." I take exception to the term "exact." The dictionary definition of exact is "suffering or exhibiting no departure from the letter or standard". Practically, it is impossible to make anything exact. The term is unsuited. What we want to do is to get an opening suitable for a nut. The A.S.A. specifications for nuts permit a tolerance in the size of the nut. We should permit a reasonable tolerance in the size of the opening. If we do not give a tolerance, the manufacturer can use his own judgment in what is his idea of exact, and we may not get what we want at all.

I recommend that this plan be revised and that suitable tolerances be indicated on the drawing. While I am still on the floor, the same thing applies to another plan which is not mentioned for revision and that is Plan No. 20 which shows the Track Gage. There again it says: "No tolerance allowed in gage distance." We want to get our track approximately correct but we certainly cannot get it exact.

In making some of the most accurate machinery, for example, ball bearings, which is about as fine work as is done, we permit a tolerance in the size of the bearings. Certainly nobody will think that a track gage needs to be made as close as a ball bearing.

Therefore, I recommend that this plan be revised and suitable tolerances for a track gage be included on the drawing.

Chairman C. J. Geyer:—For the benefit of the members, and particularly the last speaker, I believe I failed to make it clear that the plan not specifically mentioned here, (you spoke of Plan No. 4), and the other plan, have previously been adopted and printed in the Manual. We are not proposing any change in that plan this year, but the Committee will be glad to take your suggestions under advisement for future revision.

Plan No. 5, Lining Bar, dated September, 1929, revised November, 1933.

Plan No. 6, Rail Tongs, dated September, 1929, revised September, 1933.

Plan No. 9, Spike Puller, dated September, 1929, revised September, 1933.

There, again, we skip two or three plans on which we made no recommendation this year. They are already approved and in the Manual.

Plan No. 11, Claw Bars, dated September, 1932, revised September, 1933.

Plan No. 12, Track Adze, dated September, 1929, revised September, 1933.

Plan No. 13, Double Faced Sledge, dated September, 1929, revised September, 1933.

Plan No. 14, Chisel End Tamping Bar, dated September, 1929, revised September, 1933.

Plan No. 15, Spear End Tamping Bar, dated September, 1929, revised September, 1933.

Plan No. 16, Track Chisel, Design No. 1, dated September, 1929, revised September, 1933. Also Track Chisel, Design No. 2, dated September, 1929, revised September, 1931. There is no revision, I believe, in Design No. 2.

Plan No. 18, Tie Plug Punch, dated September, 1929, revised September, 1933.

Plan No. 19, Round Track Punch, dated September, 1929, revised September, 1933.

I move the adoption of these plans as recommended practice and for publication in the Manual.

The President:—The question is on the revision of the plans as shown on pages 936 to 945, inclusive. Is that correct?

Chairman C. J. Geyer:—That is correct, with the exception of those plans on which we are not making any recommendations this year. For convenience the entire set was published in the Bulletin.

The President:—To make that clear, I understand the plans shown on pages 946 and 947 will be brought up later. Are you ready for the question on the adoption of the plans previously mentioned? Is there any further discussion? All those in favor will vote "aye"; contrary. It is carried.

Chairman C. J. Geyer:—The next subject on Revision of Manual is the revision of the Book of Trackwork Plans. The Trackwork Plans covering Switches, Frogs, Crossings, etc., is one of the most important subjects before the Track Committee and one that is always with us. The last general printing of this portfolio was in 1929, five years ago.

The 1933 issue carries an index supplement of three pages, listing changes on 117 plans. It was the opinion of the Committee that, in order to make this portfolio more convenient, in fact to make it so it could be properly used by the members of the Association, all of these revisions previously approved should be brought up to date, corrections made on the basic plan. The Committee therefore spent most of the past year in making these revisions that had previously been approved and making some more or less minor additions that had not previously been brought before the Association.

The new issue which is now ready contains 176 plans. There are 14 more plans to be temporarily withdrawn until a little further work is done on them, which we think will be ready within a very short time.

The plans and specifications for special trackwork consist of data previously presented, revised, first, to include the revisions listed in the 1933 index supplement, pages 4, 5 and 6; second, to apply throughout for heavy weight rails, particularly 112-lb. RE and 131-lb. RE section, with data and specification to apply also to medium weight rails; third, to eliminate inconsistencies, also to clarify by adding new data and revising old data.

An endeavor has been made to specify on each of these plans just what will be furnished when the plan number, section of rail and detail of joint bar are specified. Unless alternates are provided or selected, the detail that shall be furnished, unless otherwise specified, has been based on what is generally recognized as good practice and is in extensive use. The alternates provided in each case cover what is also considered good practice and reported in use by two or more railroads and invite consideration for special locations and for special conditions.

An endeavor has been made to put the plans into such order that they can be readily kept up to date. The detail and sizes of bolts, for instance, are covered in Section 1402, Appendix A, and referred to but not copied on the plans.

Specifications 1402, if thought necessary later, could be revised without having to revise 100 or more plans. In the same manner, the cross-sections and details that apply throughout for a series of frog plans have been incorporated on one detailed plan so that the minor details could be revised, if found necessary, without having to revise all of the plans in the series.

While it is recognized that it is a convenience to have each of the plans complete in itself in all details, it has been found impractical to keep a series of complete plans up to date except at very great expense. As now arranged, the portfolio can be kept up to date at a reasonable cost, thus avoiding the semi-chaotic condition that has arisen in the past due to the necessity of listing in an index supplement a long list of revisions that always had to be referred to in order to intelligently make use of any of the plans.

The frog plans for heavy rails have been revised for uniform 19- $\frac{1}{2}$  in. tie spacing throughout, to apply for both heavy and medium weight rails. The lengths given have been specifically designed to suit 112-lb. RE and 131-lb. RE rails for 6-hole joint bars, and notes are given for alternate lengths that may apply for 4-hole joint bars and for medium weight rail.

The 19- $\frac{1}{2}$  in. tie spacing was adopted a number of years ago as a compromise to suit guard rails manufactured for fixed tie spacing, such as the manganese-one-piece-6-tie design, Plan No. 510. Any change in this tie spacing for frogs for replacements would result in a misfit of many thousands of guard rails now in use that have a long probable future life.

The specifications in Appendix A have been brought up to date and the material section enlarged to include data compiled from the American Standards Association. Specification E10-1929 will be found more fully outlined in Section 50, Appendix A.

As a list of necessary revisions made for consistency and to bring the plans and specifications up to date would be not only voluminous but very complicated, no attempt has been made to tabulate the revisions individually. A careful record of the plans and specifications before revision, with work sheets and correspondence relating to revisions has been kept for future reference.

The office of Mr. Fritch, Secretary, at 59 East Van Buren Street, has arranged to carry in stock new portfolios and also a supply of complete fillers to fit readily into the old looseleaf cover. These plans are now ready.

I move the adoption of the portfolio of trackwork plans as recommended practice.

The President:—It has been moved and seconded to adopt the portfolio of track-

work plans. This procedure is a little bit out of the ordinary in that it was practically impossible to submit all these plans to all the membership. The books are available, and the Committee, as I understand it, have made no very drastic changes in these plans. The changes that have been made and approved during the past years have been incorporated, and they are now asking for their approval.

Chairman C. J. Geyer:—That is correct. The only minor revisions that have now appeared have not previously been submitted.

The President:—With the assurance of the Chairman that there are only minor revisions included in these plans, the Chair will entertain that motion to adopt them, unless there is objection thereto. Do I hear any objection? The matter is then open for discussion? Are you ready for the question? All those in favor will please say "aye"; contrary. It is carried.

Chairman C. J. Geyer:—The next subject is Appendix B, Specifications for Soft Steel Track Spikes. The Chairman of the Sub-Committee, Mr. Swift, will present the report.

Mr. E. D. Swift (Belt):—The report of the Sub-Committee appears as Appendix B, pages 927 and 929, Bulletin 364.

The Committee offers the following additional sections for inclusion in the Specifications for Soft Steel Cu<sup>t</sup> Track Spikes, now appearing in the Manual at page 252.

"Tension Tests.—(a) The manufacturer may, at his option, substitute tension tests for the chemical analysis specified in Section 2, in which case the finished spikes shall conform to the following minimum requirements as to tensile properties:

|                                        |                      |
|----------------------------------------|----------------------|
| Tensile strength, lb. per sq. in. .... | 55,000               |
| Yield point, lb. per sq. in. ....      | 0.5 tensile strength |
| Elongation in 2 in., per cent .....    | 25                   |

"(b) When this option is exercised, one tension test shall be made from each 10-ton or fraction thereof.

"Copper Content.—When copper is specified, the percentage contained in the steel shall be not less than 0.20 of 1 per cent."

This matter is offered for inclusion in the Manual as additional matter to the present Specifications for Soft Steel Track Spikes. I move accordingly.

The President:—It has been moved and seconded to include this subject-matter of tension tests and copper content in the specifications for spikes. Is there any discussion on the subject? In that respect I will say that the present Manual just includes a chemical content. Are you ready for the question? All those in favor will say "aye"; contrary. It is carried and so ordered.

Mr. E. D. Swift:—The Committee presents plans for 9/16 in. and 5/8 in. spikes with raised throat as information and for criticism pending their proposed later re-submission as recommended practice.

The President:—It will be so received.

Mr. E. D. Swift:—The Committee offers as information and for criticism pending its proposed re-submission as recommended practice a proposed revision of the specifications now appearing in the Manual for Malleable Iron Tie Plates to consist of substituting the following requirements on tensile strength for the requirements now stated in the specifications:

|                                        |        |
|----------------------------------------|--------|
| Tensile strength, lb. per sq. in. .... | 53,000 |
| Elongation in 2 in. per cent .....     | 18     |
| Yield point, lb. per sq. in. ....      | 35,000 |

I might add that these requirements are considerably in excess of those stated in the present specifications but are in accord with present malleable iron practices.

The President:—It will be so received.

Chairman C. J. Geyer:—Appendix C, String lining of curves by the chord method and preparation of tables suitable for the use of trackmen. The Committee reports progress this year. Additional information does not justify a report.

Appendix D, Plans and Specifications for Track Tools, will be presented by the Chairman of the Sub-Committee, Mr. Roller.

Mr. W. L. Roller (Chesapeake & Ohio):—You will find the report of this Sub-Committee on page 930, Appendix D, Plans and Specifications for Track Tools.

In the Proceedings, Vol. 31, 1930, pages 555 to 587 inclusive, the Committee submitted the following as information and for further study:

1. General Specifications for Track Tools.
2. Specifications for Hickory Handles for Track Tools.
3. Plans and Specifications for Track Shovels.
4. Plans and Specifications for Ballast Forks.

Since that time, the Committee in collaboration with the various tool manufacturers, have revised and simplified the specifications and have brought the track shovel and ballast fork plans up to date in the light of criticism of the former plans, until we now feel that we have some definite recommendations to make, and we are recommending for adoption the following, under six items found on page 930:

(1) A.R.E.A. General Specifications for Track Tools, Plans A, B, C-1 and C-2, beginning on page 931 and continuing on pages 932 and 933. At the bottom of page 931 you will find the index under Plan A, on 932 the General Specifications for Track Tools, followed by inspection and physical tests. These specifications are not only general but are specific for each and every tool.

I move the adoption of Item No. 1, General Specifications, as covered by these plans.

The President:—You have heard the motion. Is there any discussion? All those in favor will say "aye"; contrary. It is carried.

Mr. W. L. Roller:—(2) A.R.E.A. Specifications for Hickory Handles for Track Tools, Plans D-1, D-2 and D-3, as found on pages 933 and 934.

These specifications have been before you for a number of years and we are now submitting them for adoption as recommended practice. I so move.

The President:—You have heard the motion. Is there any discussion on these specifications? All those in favor will please say "aye"; contrary. It is carried.

Mr. W. L. Roller:—(3) A.R.E.A. Specifications for Track Shovels, Plan E, found on page 935. I move the adoption of this plan and the accompanying specifications.

The President:—The Chair is confused. Are you moving the adoption of the specification and plan as shown on page 935?

Mr. W. L. Roller:—I am moving the adoption at this time of the plan itself.

The President:—It has been moved that we adopt the specification for Plan E on page 935.

Mr. W. L. Roller:—I stand corrected.

Mr. G. R. Westcott (Missouri Pacific):—I do not know whether or not most of the roads are buying shovels on A.R.E.A. specifications. I know one road that is and is having a lot of trouble. We are not using the specification that is outlined here, but if we did I suspect we might have even more trouble than we are having. I refer particularly to the paragraph covering the test. I believe this has been changed from the preceding shovel specifications of the A.R.E.A. I do not believe that the test as outlined here will develop a difficulty that has seemed very common in shovels that we have bought, that is, the failure of the shovel in the weld.

It seems to me as a general proposition that, if the A.R.E.A. specifications are to be adopted, they must be complete enough so that when materials are purchased under

them, the materials will be satisfactory. I do not believe that the test outlined here, as I said a moment ago, will determine the life of a shovel, especially in the strength of the weld if it is a welded strap shovel. I further think that the old specification, while probably better than what is shown here, would not do that.

I would suggest for the consideration of the Committee that they endeavor to develop some sort of a flexure test that will put the shovel on its merit, somewhat as the trackman does, especially when he uses it for nipping a tie.

Incidentally I want to have something to say about the handle for the shovel which is coming up a little later.

Mr. W. L. Roller:—In regard to the test which is set forth in this specification, it was considered by the Committee that this approximated the actual field test very closely and would give a fair and impartial test of the shovel itself. It may not be rigorous enough to meet the specification of the last speaker, but we would be glad to take that suggestion under advisement and consider it for future work.

The President:—Are you ready for the question? All in favor of adopting the specifications for track shovels, Plan E, say "aye"; contrary. It is carried.

Mr. W. L. Roller:—(4) A.R.E.A. Specifications for Ballast Forks, Plan F. This specification is found on page 935. I move its adoption.

The President:—It is moved and seconded that we adopt the Specifications for Ballast Forks, marked Plan F on page 935. Is there any discussion? All those in favor will say "aye"; contrary. It is carried.

Mr. W. L. Roller:—(5) A.R.E.A. Plan No. 21 dated Sept. 1933, Track Shovel, found on page 946. I move the adoption of this plan.

The President:—It has been moved and seconded to adopt the plan for track shovels shown on page 946. Is there any discussion?

Mr. G. R. Westcott:—Just one little item in this plan that from experience I have found troublesome, and that is the shape of the handle or D, so-called. The dimension of 4-in. across the D is good. The manufacturers usually like to make it less than that, and it is pretty hard to get them to come to 4-in. But to make the plan complete we ought also to show the distance from the spool to the top of the handle. They have a tendency also to reduce that dimension. I have noticed some recently that were less than 2-in., and I think that by all reasonable considerations it ought to be 2-1/2 to 2-3/4-in.

Mr. W. L. Roller:—I might say in regard to that criticism of the plan, that matter was taken under consideration by the Committee, and the dimension was omitted on purpose because of the fact that we sought to make a uniform handle for both ballast forks and shovels with a split handle and with the metal D.

Mr. G. R. Westcott:—I see no objection to specifying that dimension for both the shovel and the fork. As a matter of fact, I think it should be specified. Certainly we should give a good-sized man a chance for his fingers when we make a shovel handle for him to use. I believe that dimension ought to be shown.

Mr. W. L. Roller:—I will be glad to accept that suggestion and give it consideration in our future work.

The President:—Are you ready for the question? All those in favor of the motion to adopt the plan for shovels as recommended practice and for inclusion in the Manual will say "aye"; contrary. It is carried.

Mr. W. L. Roller:—(6) A.R.E.A. Plan No. 22, dated September 1933, Ballast Fork, found on page 947. This plan provides for two types of fork, the 10-tine and the 14-tine, providing for two individual widths of the 10-tine fork. This was so designed to meet the comments and criticism from various railroad users. I move the adoption of this plan.

The President:—Is there any discussion? All those in favor of adopting the plan for ballast forks will say "aye"; contrary. It is carried.

Mr. W. L. Roller:—The Committee wishes to submit the following correction to report of 1930 Proceedings, Vol. 31, page 587 in Conclusions: "Plan 21 dated September 1929, A.R.E.A. Wooden Track Tool Handles," should be revised to read "Plan 25, dated September 1929, A.R.E.A. Track Tool Handles."

I move that this correction be made.

The President:—The correction will be made unless there is objection thereto.

Mr. W. L. Roller:—The Committee is offering for study, criticism and for any helpful suggestions that may come, a design of Frog and Crossing Limit Gage for use in maintenance in accordance with Plan 790 adopted in 1933, as a result of study made of Standard Wheel Flanges, Treads and Gages. The design (Plan 31) as submitted is to be used only at crossings and frogs to show proper gages for the use of chilled car wheels and heavy engine drivers.

You will find that plan on the page opposite 930, which gives two separate types, one with cast aluminum ends and one with cast steel ends. Along with this plan we are submitting Plans A and B, A on the next page and B on the reverse side, showing the relation of new and worn wheel equipment and the use of this gage.

Some of these gages have been made and put into practical use, and they are found to be very helpful as a guide as to when the flangeway should be ground out to provide for the chilled car wheels. This plan and the instructions beginning at the bottom of page 930 are offered to you for information and further study.

The President:—It is so received.

Mr. W. L. Roller:—The Committee requests that the subject be continued and that a study of additional tools be made, particularly for use in the laying and handling of heavier rails.

Chairman C. J. Geyer:—Appendix E, Plans for Switches, Frogs, Crossings, Slip Switches. In the absence of the Chairman, Mr. Caruthers will submit the report.

Mr. E. W. Caruthers (Pennsylvania):—The report of the Sub-Committee is found on page 948, Bulletin 364.

The Committee presents for adoption as recommended practice Plan 505, which written plan consists of Specifications for Adjustable Guard Rail Clamps. Guard rail clamps are now in use on a number of large railroad systems, and this plan was prepared to enable railroads to obtain guard rail clamps of a more suitable and uniform design.

This plan was prepared in conference with the Standardization Committee of the Manganese Track Society.

The Committee recommends that Plan 505, A.R.E.A. Specifications for Adjustable Guard Rail Clamps, included in the revised Portfolio of Trackwork Plans, be adopted as recommended practice and printed in the Manual. I so move.

The President:—That is more a specification than a plan. It will not take long to read it, and it should be submitted to the convention. I will ask the Chairman to read it before we vote on it.

Mr. E. W. Caruthers:—"A.R.E.A. Specifications for Adjustable Guard Rail Clamps:

"(1) Clamps shall be so designed that they can be readily applied, and shall have a fit that provides a bearing against the web and under the head of both the running rail and the guard rail.

"(2) Clamps shall provide an adjustment in the width of the flangeway of at least  $\frac{1}{2}$ ", in increments not greater than  $\frac{1}{8}$ ", when used with unworn rails, the width of the flangeway shall range from  $1\frac{5}{8}$ " to  $2\frac{1}{8}$ ", however, the adjustment may be enlarged, but it must be possible to obtain  $1\frac{5}{8}$ " and  $2\frac{1}{8}$ " flangeways.

"(3) Clamp yokes shall be of rolled, forged or cast steel, and shall extend above the normal position of base of rail not less than  $4\frac{3}{8}$ " for rails over 6" high,  $3\frac{3}{4}$ " for rails 6" high and under but over 5" high, and  $3\frac{3}{8}$ " for rails 5" high and under.

"(4) Clamp yokes shall be capable of sustaining a load of 60,000 lb. without taking a permanent set of more than 0.02 in. across the jaw opening, the measurement to be taken between points marked on the normal top surface, they shall not fracture under a load of less than 90,000 lb. The load shall be applied through pivot pins at points not less than  $3\frac{1}{2}$ " above the normal position of base of rail for rails over 6" high, 3" for rails 6" high and under but over 5" high, and 2" for rails 5" high and under.

"(5) Separator blocks shall be of cast steel, cast iron or malleable iron, interlocking both vertically and horizontally, with suitable means for adjustment, and shall be so designed that they will maintain the proper position with respect to the yoke. Separator blocks and any other parts functioning against running rail or guard rail shall be of heavy design, with ample bearings against rails.

"(6) Adjusting wedges shall be of forged or cast steel or malleable iron, and suitable means shall be provided for holding them in position after they are driven tight.

"(7) For location for clamps, see data on Plans No. 503 and 504 covering details for tee-rail guard rails."

The President:—Is there any discussion? All those in favor will say "aye"; contrary. It is carried.

Chairman C. J. Geyer:—The next report, Appendix F, is only one of progress. That Sub-Committee confined all its work this year to revision of the Manual, which has been previously handled.

Appendix G, on Corrosion of Rail and Fastenings in Tunnels, the Committee reports progress.

Appendix H, Gage of Track and Elevation of Curves with Reference to the Use of Roller Bearings on Railroad Equipment. This is recommended as a final report this year, and I will ask the Chairman of the Sub-Committee, Mr. Breed, to present the report.

Mr. C. W. Breed (Burlington):—The elevation of curves must be governed primarily by the speed of trains passing over them. If the use of roller bearings because of mechanical construction were a controlling factor of the speed of trains in which they might be used, to that extent might they be an element in selecting the proper elevations of curves over which the train passed.

In order to obtain accurate information relative to the possible limits in the use of roller bearings on curves at any desired speed of operation, letters of inquiry were addressed to the large manufacturers of roller bearings, which elicited the following replies."

These replies all agree with the conclusion on page 950.

"Conclusion.—There is no different problem in the selection of the proper elevation for curves over which it is desired to operate railway equipment using roller bearings than is present if equipment is supplied with ordinary bearings."

The Mechanical Division of the A.R.A. concurred in this conclusion, and the report is submitted as information.

The President:—The report will be received as such.

Chairman C. J. Geyer:—The next report is Appendix I, Effect of Existing Materials in Track on Design of Tie Plates and Punching Thereof, together with Interrelation of Slotting of Joint Bars and Size of Track Spikes, and Appendix I-1, Design of Tie Plates for R.E. Rail Sections. This report on design of tie plates is being made for inclusion in the Manual. Mr. Macomb, Chairman of the Sub-Committee, will present the report.

Mr. J. de N. Macomb (Inland Steel):— Appendix I-1 is on page 950.

At the meeting of the Track Committee on September 21, 1933, the subject "Plans for Standard Tie Plates" was assigned.

Standard drawings of most of the larger railroads represented in the Association covering track materials were available to the Sub-Committee. From these standard drawings tabulations were prepared, showing the characteristics of the tie plates in use by these railroads with rails of various weights and sections. Studies were made of these tabulations, keeping in mind the trend toward more sturdy construction in railroad track, as a result of which the tie plate plans shown in Fig. 2 to 8, inclusive, were prepared, their principal characteristics and uses being summarized in Fig. 1.

Since the February Bulletin was issued, a meeting of the Committee was held on February 28, and certain corrections and revisions of the plans as published in the Bulletin were made.\*

On Fig. 1 enter at the foot of the sheet the following notes: "All A.R.E.A. Standard Tie Plates to be  $7\frac{1}{2}$  in. wide." That simply gives the practice shown on the drawings. They are all  $7\frac{1}{2}$  in. wide. "All A.R.E.A. Standard Tie Plates to be canted approximately 1 in 40." That also gives the practice shown on the drawings.

Then follows Note 1 at the foot of page 950 and following that Note 2. Those notes will be read in a moment. Fig. 2, 3, 4, 6 and 7, which are tie plate drawings having inclined ends, have reference marks in error. Those should be removed.

On Fig. 5 the lower outer corners of the section are to be inclined and rounded as is done in Fig. 8.

In Fig. 2, 3, 4, 6 and 7, the depth of the ribs in the anchor bottom design are shown as  $\frac{3}{16}$  in. They are reduced to  $\frac{5}{32}$  in.

Fig. 4, 5, 7 and 8, which are double shoulder tie plates, carry the following notation: "A variation of  $\frac{1}{16}$  in. over and nothing under will be permitted in the distance between shoulders."

In Fig. 2, 3, 4, 6 and 7, which are designs with inclined ends, the thicknesses of the plates with rolled crown are  $\frac{1}{32}$  in. greater at the center than the thickness of the corresponding tie plate with no camber or pressed camber.

It is thought that where the design with rolled crown is  $\frac{1}{32}$  in. thicker than the design of a section uniform across, the two sections will correspond in weight and strength better than as shown in the drawings.

Fig. 5, which is shown only as a rolled crown section, is  $\frac{27}{32}$  in. thick at the high shoulder.

Fig. 8, which is also a rolled crown section is 1 in. thick at the high shoulder, the end portions which are of uniform thickness are  $\frac{11}{16}$  in. thick.

Fig. 1 to 8, revised as just noted, together with the two notes, 1 and 2, are presented for adoption as recommended practice and printed in the Manual.

"Note 1.—Where a railroad's existing Standard Tie Plate is canted approximately 1 in 20, or has no cant (flat), A.R.E.A. standard design may be modified to correspond therewith, for use with rails having the same base width.

"Note 2.—Where existing standard spacing of spike holes, parallel to shoulder of tie plate, used with same width of rail base by any railroad, is not in accordance with A.R.E.A. standard, such existing spacing may be substituted."

I move that Fig. 1 to 8 inclusive be adopted and printed in the Manual.

The President:—You have heard the motion, gentlemen. Is there any discussion on these plans?

Mr. J. de N. Macomb:—These plans as they have been drawn have been presented to Dr. A. N. Talbot. I think he has some notes on the subject, and I hope we may hear from him.

Dr. A. N. Talbot (University of Illinois):—Although the Sub-Committee very kindly invited me to one of their meetings, I was unfortunately not able to attend, and so I do

not know what was put forward in the discussion as the purpose of certain dimensions and certain parts of the design in the tie plates recommended. I do not wish here to enter into any detailed criticism of these tie plates, but I have prepared some notes that may have a bearing upon the design of tie plates and that will help in making calculations and comparisons.

I have put down several topics, as follows:

1. The principal purpose of the tie plate, the distribution of load on the tie over the area of the tie plate at moderate intensities.
2. The bearing of the rail base on the tie plate longitudinally of the rail and the relation between this bearing and the flexure of the rail with any tilting of the tie plate and tie.
3. Strength and stiffness and length of tie plate and corresponding effect on the stresses in rail flange.
4. Bearing of tie plate on tie.
5. Bearing of rail base laterally on the tie plate.

1. **Purpose of the Tie Plate.**—It is obvious, of course, that the principal purpose of the tie plate is the distribution of load on the tie over the area of the tie plate with moderate intensities and without great variations for any load that may be applied through the rail. The amount and direction of the lateral loads or forces are quite variable. It should be kept in mind that the lateral forces on the rail act sometimes inwardly and sometimes outwardly of the track, almost as large inwardly as outwardly. Consequently sometimes there are high pressures at the outside end of the tie plate and sometimes at the inside end. The condition of the tie and the tamping also affect the direction and magnitude of the tie reaction.

A proper length of plate, then, is essential to keep down the extremes of pressure. It is best, of course, to have some eccentricity in the tie plate in such way as to cause the gage to tighten rather than widen. With the eccentricity of the tie plate in ordinary use, even a vertical force on the rail will give greater pressure on the inside end of the plate and thus tend to tighten the gage. From my own studies it has seemed that  $\frac{1}{4}$  in. would be sufficient eccentricity for the purposes of straight track and moderate curves, but the  $\frac{1}{2}$  in. given may not be troublesome and will have advantages on the sharper curves.

The purpose, then, should be to make a length sufficiently great to give a proper distribution, with not too large a pressure on the tie at either end of the tie plate, whether the lateral forces act inwardly or outwardly at any time.

2. **The Bearing of the Rail Base on the Tie Plate Longitudinally of the Rail.**—This seems to refer to the flexure of the rail as related to the tie plate and to any tilting of the plate and tie—to the bending of the rail longitudinally. I take it that with all of the ordinary widths of plate and with the heavier rails now in use, the bending of the rail under load itself has little to do with the form needed for the surface of the plate longitudinally of the rail. There is not enough flexure in the rail to affect the form of the bearing materially. If adzing of the tie or its tamping puts the plate out of plane with the base of rail, a crown or camber will relieve small inaccuracies and the resulting bearing will fall not far from the center of the tie.

Such out-of-planeness, I judge, is the principal reason for providing a camber. It would seem that a very slight camber would be sufficient for this purpose. It is certain, however, that a camber does put into the plate unconsidered stresses and renders the plate inefficient as a beam, so that the average thickness across the width would need to be greater than for a flat plate. A flat surface that gives full rail bearing all the way

across the plate has advantages over a cambered plate, and the stiffer the substructure (tie, ballast, and so forth) the less the need for the crown or camber and the greater its disadvantages. Without having heard the advantages claimed for a cambered plate I should prefer the flat plate, especially if the ties are properly adzed to the same plane for both rails.

**3. Strength and Stiffness and Length of Tie Plate, and Corresponding Effect on Stresses in the Rail Flange.**—Will the reaction pressures from the tie plate tend to break out the flange in a crescent shaped break? It has been said that making a longer tie plate adds considerably to the breaking stresses in the flange of the rail. From what calculations and study I have been able to make on this, I am not convinced that the length of the part of the plate beyond the rail has any marked effect on the stresses developed in the rail flange for the lengths of plate in ordinary use, or even somewhat greater lengths.

Analysis indicates that with a perfectly flat plate and flat rail base (meaning flat in a direction longitudinally of the tie) the main bearings of the rail flange, when the rail is loaded, are confined principally to two narrow areas lying just within the two edges of the base. There would be relatively little pressure on the plate, probably none, at the middle of the width of the rail.

From the analyses made with a given plate (see the discussion of the report of the Committee on Stresses in Railroad Track), it was found that the resultants of the pressure between plate and rail base lie about  $\frac{1}{2}$  in. inside of either edge of the base and that there is no reaction over the middle portion. It is true, of course, that the surfaces of the rail base and the plate will have imperfections and that these surfaces will vary sometimes one way and sometimes the other, but a position  $\frac{1}{2}$  in. inside the edge seems to be a proper place to locate the reactions for calculating the stresses that may come in the flange of the rail and to find whether it has sufficient strength.

With a longer length of plate, quite a long length, the resultant will be a little nearer the edge of the plate than  $\frac{1}{2}$  in., but the magnitude of the upward reaction will not change much and so the stresses in the flange of the rail will not vary greatly.

The thickness of the plate, of course, should be great enough to keep the deflection of the plate within reasonable limits. I do not see that the stresses in the rail flange will be affected very greatly by the usual range in the dimensions of the plate itself.

One other thing in regard to these crescent shaped breaks—after hearing a great deal about them I have come to the belief that the breakage of rail flanges results from high loads on certain ties with the applied load force directed in such a way that almost all the load is carried on or near one edge of the base of rail, or that the condition of the ties and their bearings are such that most of the tie reaction necessarily passes through this point. Under the first condition there may then be such a large lateral force combined with an undue vertical load on one or more ties that the load applied is large and has a large sidewise component, just as though the rail were tilted; or under a second condition that would produce the same effect, the position of the tie plate and tie is such that one edge of the rail receives practically all of the tie reaction—that is, the trouble comes from a condition of the track or the loading and not by reason of the design of the tie plate except as the tie plate is too small.

**4. Bearing of the Tie Plate on Tie.**—On the general question of tie bearing, I am a believer in the advantages attained by spending effort and money too in adzing the tie in such a way as to get the bearing surfaces of the ties for the two rails accurately in the same plane.

I also think that spiking the tie plate effectively to the tie has great advantages from a maintenance and economical viewpoint. More nearly perfect bearings on the tie, less mechanical wear, greatly improved and more uniform rail support will be effected.

I think, too, that anchor ribs have objectionable features. With the rib construction the plate will not fully seat on the tie and the bearing will not be uniform over the whole area of the tie plate. The detrusion of the metal into the wood makes opportunity for breaking the fibers and starting decay. With the added friction between flange and tie plate secured by spiking the tie plate closely to the tie and the lateral holding power of the spikes, lateral resistance is provided so that it will not be necessary, I think, to give further anchorage.

5. **Bearing of the Rail Base Laterally on the Tie Plate.**—The bearing between the metal surfaces of the rail and tie plate transversely of the rail will not be perfect and the tolerances used would seem to be comparatively large—that is to be expected. A convex surface in either rail base or tie plate will allow rocking of the rail laterally. No one has advocated a concave surface in either rail or plate, though that would insure definite bearing. A wood plate or shim between the base of the rail and the tie plate seems to have advantages.

Dr. von Schrenk reports that the use of compressed wood plates, where tried out in this country, has proven practical and effective. I think you will agree that this arrangement, if it is practical, will overcome unevenness of the metal surfaces that are bound to be uneven and will give adjustment for some out-of-planeness of tie and rail bearings—and there is a great deal of out-of-planeness at the present time and a little of it makes an increase in rail stresses and distortions. The improved bearing will decrease the stress in rail flanges because of bringing the resultant of the reaction farther in from the edge of the rail. It obviates need for crown or camber. Even if the elasticity of the wood proves not to be available for a cushioning effect, the wood does give an adjusting medium there.

The presence of double shoulders on the tie plates, which should preferably be used with the wood plates, gives other advantages to the track. It should not be overlooked in this respect that high lateral forces act on the rail inwardly of the track as well as outwardly, and if the rail is held closely to place when the pull is inward, by means of the shoulders, a decrease in the lateral force applied to the other rail will result and the side thrust will be divided more evenly between the two rails.

It would seem well, then, to try out the wooden plates more extensively and to evaluate their advantages.

Finally, let me express the view that there are other features in track that contribute to the need for large, heavy tie plates. One is the presence of seasoning checks and shakes and cracks in the tie. It is surprising to see to what extent the ordinary checks increase the deflection and depression of the plate into the wood and produce irregularity in bearing resistance at different parts of the plate. As these checks can hardly be avoided, the alternative is to provide adequate bearing area in the tie plate and sufficient thickness.

Mr. L. W. Skov (Burlington):—In 1932 the Burlington Railroad had a number of rail base failures. This caused an order to be given to investigate our tie plate designs to determine if they in any way were the cause of the failures.

Quite extensive tests were made on several types of tie plates resting on various kinds of timber. The tests were run at our Aurora laboratories. Inspections were also made of tracks to see how the plates behaved in actual service.

The main object of the tests was to determine the effect, if any, the tie plates had on the transverse stresses in the rail base. In order to determine these effects it was

necessary, first, to make a determination of the modulus of elasticity of various kinds of wood used in ties. Next the deflections of the rail base, tie plate and tie were determined, at right angles, to the rail web.

I have listened to Dr. Talbot's discussion, and agree fully with what he has said; however, there are one or two things I would like to add.

The tie plates that we tested were all  $7\frac{1}{2}$  by  $\frac{1}{2}$ -inch plates. They were of various bottom designs and the plates varied some in thickness. One hundred pound rail was used throughout the entire test. I agree with Dr. Talbot's statement about the transverse stress produced in the rail bases. He did not tie it down to a definite figure but permitted some variation.

Stresses from 30,000 to 38,000 lb. per sq. in. were produced in the rail base at right angles to the web, when the tie plates rested on white oak ties. Other hardwoods having the same modulus of elasticity perpendicular to the grain will produce like stresses in the tie plate and rail base.

While stresses of the above magnitude are within the strength of the steel in the rails, they are not the only stresses present in actual service, and when combined with such other stresses, the resultant might well stress the steel beyond safe limits.

High transverse stresses in the rail base are objectionable on account of the tendency for seams, however small, along the center line of the rail base.

A number of rails were sent to the laboratory and there loaded until base failure occurred. A number of these rails had longitudinal cracks along the center of the web, ranging in depth from  $1/16$  in. to 1 in.

They always occurred over the tie plate, and they always occurred where the rail showed bearing marks along the edges only. In other words, the rails showed progressive failure where the base received most of the load near its edges.

While the stresses that we found are no higher than the steel should be able to withstand, we have been wondering if, in the cases where the rail does not have full bearing on the tie plate, under the lighter loads, there is a tendency for this often repeated high stress along with the unavoidable seams along the center of the web to produce rail base failure.

In order to determine this, I am satisfied that more study would have to be given to the subject than we could give and did give, but it did occur to me, from the rails investigated, that there is something worth investigating.

Referring to the tie plates, the tests were made in two ways. First, the plates were placed on the ties and loaded. In the second set of tests the plates were bedded on a thin layer of plaster of paris, in order to secure a uniform bearing throughout similar to a fully seated condition. It was realized that in track there are many conditions that are not perfect, but in order to make a test that would permit of proper evaluation it, of course, was necessary to make it as nearly perfect as possible.

With transverse stresses in the rail base of from 30,000 to 38,000 lb., the edge of the rail would deflect upward about 0.004 in., the edge of the tie plate would deflect upward from about 0.028 to about 0.05 in., depending on the type of the plate and on the kind of wood in the tie. In oak ties the timber at or near the center of the rail would be loaded to about 620 to 630 lb. per sq. in., whereas at the edge of the tie would be loaded to less than 300 lb. per sq. in. In the softwood ties such as pine and fir, the condition is somewhat reversed, because the strength of that type of wood, transverse to the grain, is less than 300 lb. per sq. in. If the stress is over that, it is beyond the elastic limit. Fortunately, lumber possesses the same properties as does steel. It can be overstressed a number of times and actually gets stronger. I do not believe that information as to this

property has been published yet, but a good deal of work has been done on it at Madison in the Forest Products Laboratory, and their work seems to bear out our findings.

In view of the high tie stresses, it seems advisable to have the metal so proportioned as to give the most uniform tie loading possible. This can best be accomplished by making the plate as wide as possible, this form of plate also reducing the rail base stress to a minimum.

The President:—Is there any further discussion on this subject of tie plates?

Mr. W. J. Burton (Missouri Pacific):—I understood Major Macomb to say that these recommended tie plates are compromises, or averages, which have been derived from present practice. It seems to me that this is the wrong way to go about a subject of this kind. Certainly, if we do nothing but recommend what we have been doing, we will have no progress.

I listened to what Dr. Talbot said and to what the previous speaker has said, and I am very certain that we have a good deal to learn yet, and there is a good deal of room for improvement in our tie plate design.

I am particularly interested, from the standpoint of the tie, in the shape of the bottom of the plate. I have in mind the work which the Stresses in Track Committee has done in pointing out the undesirable characteristics of tie plates which are not flat but which require varying amounts of traffic to seat, and the undesirable effect of having one tie plate fully seated, and the one on the next tie not fully seated, causing a variation in the support of the rail from tie to tie. One tie will be soft; the plate will sink into that tie, perhaps, under the passage of the first train. The next tie may be hard, and it may take considerable traffic before it is seated, or, it may never be fully seated. One end of the first tie may have a knot running out at the rail seat; the other end may be free of any knot, etc. I am speaking particularly of ties that are pre-adzed, because they are used almost universally now.

This is only one, however, of the several thoughts that come to mind in considering this report of the Committee. I am therefore very hopeful that the Committee will give this subject further study before recommending for inclusion in the Manual.

Putting the present report in the Manual will not improve what we are already doing, because, as Major Macomb has said, the report and the designs are merely compromises, if you please, of present practice. As I see it no great loss will result from holding it over another year and giving further study to the subject.

The President:—Are you ready for the question?

Mr. L. W. Skov:—I would just like to say one more word that was brought to my attention by the last speaker. In our investigation we also tried to determine how long it took for tie plates to seat. On our main line it appeared that it took about two years. The way it was tested was by placing paper along the track under the tie plates, letting a train go across and then seeing how much the tie plate was bearing at the tie. A good percentage of the tie plates take from one to two years before they are fully seated on the ties. Softwood ties, of course, seat much faster. The ordinary ribs on the bottom of tie plates will require about 30,000 lb. to seat them.

The President:—Are you ready for the question? The motion is to adopt the plans shown in the report, on tie plates. All those in favor will say "aye"; contrary. The "ayes" appear to have it, but the Chair is undecided. I will ask for a division of the vote. Those in favor will please stand; contrary-minded will please stand. The motion is lost.

Mr. John V. Neubert (New York Central):—Mr. Wiltsee, Major Macomb and his Committee have done some very excellent work, they have done some very hard work. I was on that Sub-Committee and I did not vote either way. I do not know what

pressure there is to speed up the design of this tie plate, but what leads me to speak now is I believe there are six members on the Sub-Committee who voted against it. There is a little difference of opinion. You have a big problem here, and the tie plate is a big factor in this problem.

I am glad that this subject is carried over for another year because I think you will come to something that is going to be a little more definite than the tie plate we now have.

Mr. J. de N. Macomb:—Appendix I, page 950, effect of existing materials in track on design of tie plates and punching thereof, together with interrelation of slotting of joint bars, and size of track spikes. That subject has been continued for several years, but the work now being done on tie plates by the Track Committee and on joint bars by the Rail Committee, has made it undesirable to try to press the work at this time, and it is recommended that this subject be discontinued.

The President:—The Outline of Work Committee will consider the recommendation.

Chairman C. J. Geyer:—Appendix J, practicability of using reflex units for switch lamps and targets. This is simply a report of information, following out previous reports on this subject.

Appendix K, selective welding up at joints, instead of welding out of face. This report is submitted as information.

Appendix L, desirable tightness of track joints and effect upon the life of rails and joints of overtight joints; of loose joints. This report is submitted as information with the recommendation that the subject be discontinued.

The President:—The Outline of Work Committee will give consideration to that.

Chairman C. J. Geyer:—Appendix M, reclamation of serviceable materials from scrap and retired maintenance of way and structure machines, tools and appliances. There is no report this year.

Appendix N, methods of reconditioning of rail ends, fastenings, frogs and switches in track. This report is submitted as information. The Committee believes that this assignment is a very important subject and recommends that it be continued.

Appendix O, determination of the limiting relative positions of the abutting rails of fixed and drawspans on bridges and proper tolerances. That is only a progress report for this year.

Appendix P, damage to track and devices due to brine drippings from refrigerator cars. In this report the Committee has collaborated with the Mechanical Division, and the Sub-Committee from that Division joins in this report, giving information as outlined in the report.

“Recommendation.—A higher degree of maintenance of tanks and fittings on existing brine tank equipment and better protection of tracks, bridges and signals against brine drippings. Under existing circumstances, this seems the most economical and practical procedure.

“It is recommended that the subject be dropped, at least until such time as there are developments which would make it worth while to revive this subject.”

This is simply a continuation of informative reports published in previous Bulletins.

That completes the Track Committee's report.

The President:—This Committee has done an immense amount of work this year. If you realize the work on the track plans and on the track tools, and the work they have done on the tie plates, which was only started the latter part of the year, it is very evident that they have been very active. I wish to compliment them on the work they have done. We now dismiss them with the thanks of the Association (Applause).

## DISCUSSION ON BUILDINGS

(For Report, see pp. 529-559)

(Vice-President John E. Armstrong in the Chair.)

Mr. G. A. Rodman (New Haven):—The report of the Committee on Buildings will be found in Bulletin 361, page 529. We have ten subjects under consideration. On five of these we assembled data but not sufficient material to make a report this year. We recommend the reassignment this year of:

(4) Bus Terminal Buildings. (5) Application of Stainless and Rust-Resisting Metals to Building Construction. (7) Vermin and Rat-proofing in Buildings. (9) Mill type and other heavy wood construction for railway buildings. (10) Study the economic value of various basic and composite materials used in building construction and maintenance.

On (1) Revision of Manual, we will have the report presented by Mr. Wilbur.

Mr. O. G. Wilbur (Baltimore & Ohio):—The recommendations of the Committee pertaining to revisions in the Manual will be found on pages 530 to 540, inclusive, of Bulletin 361.

The Committee recommends that on page 316 of the Manual, under Section 10-A, Concrete Roofing Tile, the text be revised to read as follows:

"The joints of large flat tile shall be pointed where necessary so as to provide a smooth surface for the application of the roofing."

Other revisions recommended concern the specifications for built-up roofing on pages 319 to 327, inclusive, of the Manual, under Section 10-D. They cover specifications for various types of built-up roofing on the several classes of roof structures or decks. These specifications have been revised as to form, and in the eight types involved all have been fully framed so that the eight types are consistent with each other. The matter of flashing is covered more thoroughly in the revised specifications than it is now covered in the Manual.

These revisions have been made in order that the specifications will conform to present-day practice. They have been submitted to various roofing manufacturers and contractors who apply roofing, and the Committee has been advised by both that the specifications as revised are in keeping with good practice.

Since these revisions have been in the hands of the membership since the issuance of the November Bulletin, I shall read only the headings and pause briefly for questions.

The Committee recommends, and I so move, that the changes in the Manual as recommended in Appendix A, beginning on page 530 of Bulletin 361, be approved, and the revised text be substituted for that now appearing in the Manual:

Page 530, Materials. Page 532, Type A-1, Tarred Rag Felt, Pitch and Gravel (or Slag) Over Wood or Pre-Cast Units. Page 533, Type A-2, Tarred Rag Felt, Pitch and Gravel (or Slag) Over Homogeneous Roofs Cast in Place. Page 534, Asphalt Rag Felt, Asphalt and Gravel (or Slag) Over Wood or Pre-Cast Units. Page 535, Type B-2, Asphalt Rag Felt, Asphalt and Gravel (or Slag) Over Homogeneous Roofs Cast in Place. Page 536, Type C-1 (Class 2), Asphalt Impregnated Asbestos Felt and Asphalt (Smooth Surface) Over Wood or Pre-Cast Units. Page 537, Type C-1 (Class 3), Asphalt Saturated Rag Felt, Asphalt Impregnated Asbestos Felt and Asphalt (Smooth Surface) Over Wood or Pre-Cast Units. Page 538, Type C-2 (Class 2), Asphalt Impregnated Asbestos Felt and Asphalt (Smooth Surface) Over Homogeneous Roofs Cast in Place. Page 539, Type C-2 (Class 3), Asphalt Saturated Rag Felt, Asphalt Impregnated Asbestos Felt and Asphalt (Smooth Surface) Over Homogeneous Units Cast in Place.

Vice-President John E. Armstrong:—I understood your motion to include revisions in 10-A and 10-D.

Mr. O. G. Wilbur:—Yes, 10-A and 10-D as indicated in Appendix A.

Mr. W. A. Radspinner (Chesapeake & Ohio):—If you apply for insurance on a building, a representative comes to your property to inspect it and give you an insurance rating. If your building has built-up roofing that does not carry the Underwriters' label, you will probably be penalized on your insurance rates.

Mr. O. G. Wilbur:—There is nothing in the specifications which, as I understand it, will prevent you from being given a rating.

Mr. W. A. Radspinner:—Have they collaborated with the National Board of Underwriters and the Underwriters Laboratories in that respect? These labels are put out by the Underwriters Laboratories, and whenever a manufacturer buys roofing of any kind he pays for that label. The Underwriters label and their specification is one that is generally used by contractors when they buy roofing. The laboratories put out little books periodically listing roofings that carry that label. I do not know for sure about this, but I am pretty certain that if you are building a building and put on a roof, if you do not use Underwriters specifications or roofing carrying the Underwriters' label you have to pay for the difference in your insurance.

Mr. O. G. Wilbur:—It is our understanding that the question of rating only covers the material and not the application of the material.

Vice-President John E. Armstrong:—Is there any further discussion? Are you ready for the question? Those in favor signify by saying "aye"; opposed likewise. The motion is carried.

Chairman G. A. Rodman:—Subject (2), Preparation of Specifications for Railway Buildings, will be presented by Mr. Judd.

Mr. F. R. Judd (Illinois Central):—You will find the report on this subject under Appendix B, pages 540 to 551, Bulletin 361.

The Committee submits for publication in the Manual, Specifications for Electrically Operated Freight or Baggage Elevators. These specifications were presented to the last convention and have been in printed form since a year ago February. The Committee has received no unfavorable comments, and we are therefore offering these specifications for publication in the Manual, and I so move.

Vice-President John E. Armstrong:—Will you read it by general headings?

Mr. F. R. Judd:—The specifications will be found in Bulletin 354 published February, 1933, page 682. The headings are:

1. General. 2. Checking drawings. 3. Laying out work. 4. System. 5. Car platform. 6. Car cover. 7. Car frame. 8. Hatchways and shaft enclosure. 9. Hoisting machine. 10. Overhead sheaves. 11. Lifting cables. 12. Counterweights. 13. Guide posts and guides. 14. Control. 15. Operating device. 16. Buffers. 17. Elevator doors or gates. 18. Governor and safety device. 19. Limit switches. 20. Safety switch. 21. Foundations and supports. 22. Lubricators. 23. Screens and ladders. 24. Electrical equipment. 25. Signal system. 26. Lighting car. 27. Cable lock. 28. Lubricants. 29. Prosecution of work. 30. Cutting. 31. Painting. 32. Instructing operator and railroad. 33. List of parts. 34. Guarantee. 35. Inspection. 36. Final inspection and test. 37. Laws and ordinances. 38. Cleaning. 39. General conditions.

Vice-President John E. Armstrong:—This is a specification which has been before you for a year for consideration. Are you ready for the question?

Mr. J. C. Irwin (Boston & Albany):—Mr. Judd has outlined a few provisions that are distinctly contract provisions. We have repeatedly made the distinction between specifications and contract provisions as defined in the Manual.

I suggest that those few provisions which are not necessary in connection with the specifications, and which are found in contract forms should be eliminated before this is approved for the Manual, to avoid duplication and also probable conflict.

Mr. F. R. Judd:—I would like to bring the matter before the Association that this question was settled a number of years ago. We already have something like thirty specifications in the Manual. The question of these clauses being both in the specification and in the contract was brought up on the floor of this convention, I think, some six or eight years ago, and at that time it was decided that as long as there was no conflict with the contract, they should remain. So the Committee has been consistent throughout in living up to the instructions they received at that time.

If we are going to change that in any one specification we would have to go through the Manual and, to be consistent, take those same clauses out of probably thirty specifications that are already accepted.

I think the decision of this Association at a previous convention should be recognized at this time, and we should probably continue with the present practice.

Mr. J. C. Irwin:—I make no objection, if they in accordance with those already in the Manual. I have not checked them. Yet I thought that Mr. Judd had cited a few which were distinctly contract provisions. My recollection is that the committees have been instructed in the convention and also in their outline of work to avoid the contract provisions. In this case I ask Mr. Judd to mention the last two or three of those and state whether they are contract provisions in the uniform contract forms.

Mr. F. R. Judd:—You mean to read the particular clauses?

Mr. J. C. Irwin:—I mean the headings about inspection.

Mr. F. R. Judd:—Final Inspection and Test. The wording under that does not conflict with the requirements of the contract.

Mr. J. C. Irwin:—I make no further objection if Mr. Judd is satisfied with that. I have not checked it. I simply state the general principle that the contract provisions should be avoided. In this case I would not wish to prevent their going through, but it may be reconsidered in connection with the revisions and the elimination of duplications in the Manual. At the present time I make no further objection.

Vice-President John E. Armstrong:—Is that a matter that might be taken care of by the Manual Committee as they go through that?

Mr. J. C. Irwin:—I think so.

Vice-President John E. Armstrong:—Is there any further discussion? Are you ready for the question? Those in favor signify by saying "aye"; contrary likewise. The motion is carried.

Mr. F. R. Judd:—The Committee further submits at this time the following specifications: Section 30-D, Steel Chimneys—Welded. Section 30-E, Genuine Wrought Iron Chimneys. Section 10-D, Built-up Roofing, Type C-1 (Class 1), and Type C-2 (Class 1). Section 31-A, Wood Screens, and 31-B, Metal Screens.

These specifications are offered as information.

Vice-President John E. Armstrong:—They will be so received.

Chairman G. A. Rodman:—Subject (3), Remodeling Freight Houses for Accommodation of Truck Door-to-Door Delivery of Freight. The report will be presented by Mr. Irwin.

Mr. A. C. Irwin (Portland Cement Association):—I will read the first two paragraphs because they constitute a conclusion made by the Sub-Committee.

"All l.c.l. freight is, to all intents and purposes, a door-to-door delivery, either by individual trucks or trucking companies.

"Existing freight houses usually have tracks on one or both sides for the loading or unloading of freight cars. Generally, on one side is the tailboard space, with or

without platform, for trucks or other vehicles delivering or receiving freight. The same arrangement should meet the requirements of the door-to-door system, consequently it is unnecessary to remodel existing freight houses materially, if any. All that is involved is a change in responsibility and operation."

The recommendation of the Committee is that this subject be discontinued.

Vice-President John E. Armstrong:—The recommendation is that the submission be accepted as information and the subject discontinued. It will be accepted as information and will be discontinued or not, according to the decision of the Committee on Outline of Work.

Chairman G. A. Rodman:—Subject (7), Relative Merits of Wood and Fireproof Roof Structures, which includes Wood, Hollow Tile Fire-proofing, Concrete and Cement Tile, etc. Mr. Upson will present the report.

Mr. A. T. Upson (American Forest Products Industries, Inc.):—This subject has been before the Committee for two years. During that time a great deal of study has been given the subject in order to bring out all the practical and scientific data available and, at the same time, to present the resulting information in a form that will make it of the greatest use to Building Engineers. That has resulted in the report under Appendix G, on page 552.

You will see that it first takes up and describes very briefly each of the twenty-one different types of materials used singly, or in combination with other materials, for roof decking. It then attempts to rate these twenty-one types of decks from their ten different property standpoints.

We believe that the information as presented will furnish a reliable guide to the Building Engineer in the selection of roof decks for different types of buildings. It is offered as information.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman G. A. Rodman:—Subject (8), Causes of Dust Explosions in Grain Elevators and Methods of Obviating the Hazard. The report will be presented by Mr. Stone.

Mr. A. B. Stone (Norfolk & Western):—The report of the Sub-Committee on Causes of Dust Explosions in Grain Elevators and Methods of Obviating the Hazard is under Appendix H, pages 554 to 559, Bulletin 361.

The conclusions reached by the Committee, as indicated on page 558, are as follows:

"The hazards of dust explosions can be reduced by—

"(1) Good housekeeping to prevent accumulation of static dust.

"(2) Dust-tight electric equipment.

"(3) Plenty of ventilation to prevent atmosphere from becoming charged with explosive dust.

"(4) Dust collection by fan produced suction—to remove dust in suspension at all points where grain is agitated."

The Committee recommends that this report be accepted as information.

Vice-President John E. Armstrong:—If there is no objection, it will be so received.

Chairman G. A. Rodman:—That completes the report of the Buildings Committee.

Vice-President John E. Armstrong:—Gentlemen, as usual, the Buildings Committee has turned out an excellent report. They will be excused with the thanks of the Association (Applause).

Mr. E. E. R. Tratman (Civil Engineer—by letter):—The report of the Sub-Committee on the remodeling of freight houses for accommodation of door-to-door delivery of freight, page 551, says that "all l.c.l. freight is to all intents and purposes door-to-door delivery, either by individual trucks or trucking companies". This does not seem to be

quite correct or to cover the situation, since in railroad parlance "door-to-door service" implies handling from consignor's door to consignee's door by or under direct responsibility of the railroad. Apparently it was this fact that led to the subject being assigned for committee consideration. Whether any remodeling of freight houses would be required or advantageous for "door-to-door" service where the railroad operates (or controls) the service between the "doors" and the freight houses, is not touched upon in the report.

## DISCUSSION ON SHOPS AND LOCOMOTIVE TERMINALS

(For Report, see pp. 403-417)

(Vice-President John E. Armstrong in the Chair.)

Mr. J. M. Metcalf (Missouri-Kansas-Texas):—The report of the Committee this year is found in Bulletin 360 beginning on page 403.

The Committee has no recommendations to make for revision of the Manual this year. It reports progress on the following subjects:

(2) Welding Equipment Installations as Applied to Shops and Locomotive Terminals.

(3) General Reclamation Plants.

(7) Car Wheel Shops.

It is making a report on Subject (4) Turntables, which will be presented by Mr. Kimball, Chairman of the Sub-Committee.

Mr. L. P. Kimball (Baltimore & Ohio):—The report of this Sub-Committee will be found in Appendix A, beginning on page 403. This report is a continuation of the report of the same Committee made last year, in which all but one of the recommendations as then presented were accepted by the Association for inclusion in the Manual. This one conclusion, identified as No. 3, was referred back to the Committee for further consideration.

The Committee made a detailed investigation of the general practice of railroads in regard to this subject, which is the method of making connection to the electrical apparatus for operating the turntables, and the results of this investigation are shown in the questionnaire as tabulated on pages 404 and 405. As a result of the information contained in the replies to the questionnaire, the Committee has revised their former Conclusion No. 3 as previously submitted, and recommends that the conclusion as now appearing at the bottom of page 405 be accepted by the Association for inclusion in the Manual. This conclusion reads as follows:

"Where modern locomotives are to be turned, mechanical power for operating turntables should be provided. Where current is available, electricity is the most reliable means of operating a turntable. The power wires may be led to the table, either overhead or underground. In either type care should be taken to see that installation is made so as to minimize the danger of interruption in case of fire, storm, inadequate drainage or other emergency. Where electric power is not available, a compressed air motor may be used."

I move that this conclusion be accepted for publication in the Manual with the other conclusions accepted last year.

Vice-President John E. Armstrong:—You have heard the motion and the second, gentlemen. Is there any discussion? If not, those in favor signify by saying "aye"; opposed likewise. The motion is carried.

Chairman J. M. Metcalf:—On Subject (5), Power Plants, the Committee submits a progress report printed on pages 406 to 409, inclusive and asks that the subject be continued for further study.

Vice-President John E. Armstrong:—It will be so arranged.

Chairman J. M. Metcalf:—On Subject (6), Wheel-Removing Equipment for Engine Houses, the report will be presented by Mr. Hawk, Chairman of the Sub-Committee.

Mr. A. T. Hawk (Rock Island):—The report on Wheel-Removing Equipment for Engine Houses is shown on pages 409 to 414 inclusive. The first part covers the Evolution of Drop Pit Equipment, shown on pages 409 and 410, and a general description of Drop Tables shown on page 411. At the bottom of this page is shown the special points of advantage of drop tables. Page 412 gives the general requirements for drop tables; 413 shows an illustration of a typical layout where three drop tables are used, one for tender truck, one for drivers and trailers and the other for engine trucks. Page 414 shows a typical layout where only one drop pit is used for handling all classes of wheels. The dotted lines indicate what might be done in the way of lengthening the stalls, and a new location for the drop table so that an engine might be entirely enclosed in the engine house when undergoing repairs necessitating removal of wheels.

This report is given as information, and it is asked to have it published in the Proceedings.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman J. M. Metcalf:—The report on Subject (8), Car Paint Shops, will be presented by Mr. Dorland, Chairman of the Sub-Committee.

Mr. A. G. Dorland (Elgin, Joliet & Eastern):—The report of the Sub-Committee on Car Paint Shops is shown as Appendix G, pages 415 to 417.

I wish to call your attention to a correction at the bottom of page 415 in the last line. It should read "twelve and one-half days" instead of "twelve and one-fourth days."

On page 416, in the first paragraph, the capacity of the shop is shown on a percentage basis. The Sub-Committee has been asked to show how we derived the formula for these figures.

Our questionnaires asked for the number of cars in service normally, the number painted annually and the number of days in the shop. The formula was derived as follows: By multiplying the number of cars painted annually by the number of days in the shop, this result to be divided by the product of number of cars in service and 280 (the latter representing the number of days shop is operated annually).

The report is submitted as information, and I suggest that the subject be continued.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman J. M. Metcalf:—That concludes the report.

Vice-President John E. Armstrong:—Although there is very little Manual material in this report this year, there is a mass of concentrated information. In excusing the Committee with the thanks of the Association, I wish to compliment them (Applause).

## DISCUSSION ON MAINTENANCE OF WAY WORK EQUIPMENT

(For Report, see pp. 473-520)

(Vice-President John E. Armstrong in the Chair.)

Mr. C. R. Knowles (Illinois Central):—The report of Committee XXVII—Maintenance of Way Work Equipment, appears on page 473 of Bulletin 361.

The Committee reports progress on the following subjects:

- (1) Revision of Manual.
- (6) Methods of keeping data on work equipment and labor-saving devices.

- (7) The selection and training of maintainers and operators of work equipment.
- (8) Use of ballast discers.
- (9) Organization for the use of tie-tamping machines, air and electric.
- (10) Rail laying machines and auxiliary equipment.
- (12) Tie adzing, scoring and boring machines.
- (14) Prepare manual of instructions for care and operation of maintenance of way work equipment.
- (17) Use of oil spraying machines for oiling rails and fastenings, steel structures and roadbed.

The report of Sub-Committee (3) on Track Grinders appears on page 475. Mr. Bowen, Chairman of the Sub-Committee, will present the report.

There is an error on page 473, Subject (2), Standardization of parts and accessories for railway maintenance motor cars. The paragraph carries the recommendation that the report be adopted for publication in the Manual. At the last moment the report was withdrawn, and the Committee merely reports progress.

Mr. M. D. Bowen (Milwaukee):—The subject, Adaptability of Air and Electric Driven Tools in Maintenance of Way Work, perhaps does not cover exactly the work of the Sub-Committee, which was later assigned to them under the heading "Track Grinders". It is a new subject, and, of course, grinding done in connection with rail welding is somewhat newer than rail welding itself.

For that reason there is a good deal of work yet to be done relative to the development of the machine and the carrying out of the work that the machines have to do. Any information contained in the tentative report is submitted more for the information of the railroads doing that type of work than with the thought of being considered a definite report.

Questionnaires were sent out to nearly all of the railroads and to all manufacturers that were at that time known to be manufacturing track grinding machines. Numerous pictures of various machines were published as a matter of information to those interested in track grinding.

The report as submitted contains information available at this time. Numerous developments are now under way, and we expect to report on them in the future as the information develops.

Vice-President John E. Armstrong:—The report will be accepted as information.

Chairman C. R. Knowles:—The report of Sub-Committee (4) on Snow-Melting Devices appears on page 482. This report covers additions to last year's report on the same subject and includes a few changes in that report. The several numbers under the heading of Types and Bibliography tie in with last year's report.

The report is submitted as information.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman C. R. Knowles:—The report of Sub-Committee (5) on Track Type Tractors, with special reference to front end loaders, appears on page 485. Mr. Pittman, Chairman of the Sub-Committee, will present this report.

Mr. T. M. Pittman (Illinois Central):—The report of Sub-Committee (5), Use and Adaptability of Track Type Tractors in Maintenance of Way Work, will be found on pages 485 to 498. This is a continuation of last year's report.

Last year the report gave a general description of track type tractors and some of the interchangeable attachments by which they can be better adapted to special classes of work.

This report gives a more detailed description of two of those attachments, the front end loader on pages 485 to 488, and air compressors on pages 488 to 492.

The remainder of the report shown in Part II gives a suggested scoring sheet for track type tractors. The aim of this sheet is to insure that all makes of tractors being considered will be graded on the same features, which are listed, to avoid their being overlooked. This will result in a more intelligent comparison of the machines. The sheet, however, should be adjusted to fit particular needs or conditions on individual roads. The report is submitted as information with the recommendation that the subject be reassigned and continued for the next year.

Vice-President John E. Armstrong:—The report will be so received.

Chairman C. R. Knowles:—The report of Sub-Committee (11) on Weed Destroying Equipment appears on page 498. This report is a résumé of information available in regard to weed destroying equipment, including hand methods, chemical weed killers, non-poisonous powder, steam weed destroyers, mowing machines, ballast discers and weed burners.

This report is submitted as information.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman C. R. Knowles:—Report of Sub-Committee (13), Track Welding Equipment, appears on page 504. Mr. Trissal, Chairman of the Sub-Committee, will present the report.

Mr. J. M. Trissal (Illinois Central):—In studying this subject your Committee has endeavored to set up certain fundamental differences between oxy-acetylene and arc welding, and to give general information relative to the equipment employed in performing both types of welding. Certain of the facts developed favor oxy-acetylene welding from an economic standpoint, and others favor electric arc welding. Both types of welding can be employed with equal success on track work, except manganese, the welding of which requires the use of the electric arc.

The use of the multiple tip flame in gas welding, with the attendant increase in rate of depositing metal, has been considered.

A comparison is made between the alternating current and direct current type of electric arc welding machine. A further comparison is made between the constant potential and variable potential direct current electric welding equipment. Particular study has been given the method of making portable the variable potential types of electric arc welding equipment, attention being called to several specific methods employed by railroads.

A table showing the voltage drop which may be expected in various lengths of cable, with various currents, is included in the report.

This report is submitted as information.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman C. R. Knowles:—The report of Sub-Committee (15), on the Use and Maintenance of Paint Spraying Equipment, together with Appendix H, Hazards of Spray Painting, appears on page 510.

This report is a continuation of the report previously submitted by the Committee and covers a study of a concrete case of spray painting. The Committee also presents on page 513 a compilation of information available on the hazards of spray painting. This report is submitted as information.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman C. R. Knowles:—Report of Committee (16), Organization for the Use and Maintenance of Ballast Cleaning Machines, appears on page 516. Mr. Elmer, Chairman of the Committee, will present the report.

Mr. William Elmer (Pennsylvania):—Since our report in Vol. 33 of the Proceedings there has been completed and placed in service a two-sided ballast cleaning machine which picks up the dirt and ballast from the intertrack space or border, or both, screening and placing back the clean stone, and disposing of the dirt by means of a belt conveyor across one track and over the shoulder, if working on a fill, or storing the dirt in a large bin constructed over two flat cars, if working in cuts. The dirt can be moved out of the bin and fed to the conveyor when the machine is again working on a fill. The operating expense runs about 3 to 5 cents per foot, and the output is estimated to be in the neighborhood of 100 miles of center ditch cleaned each month.

Another improved machine brought out since our former report is a combination scarifier and blader adapted to work in stone valleys and shoulders. This machine is self-contained and self-propelled on a heavy track motor car and embodies wings which may be lowered on either or both sides by means of a pneumatic hoist, and the ballast can be thrown out and later thrown back, with a considerable portion of the dirt removed, and shaped up against the ends of the ties to approximately correct shoulder section.

This report is submitted as information.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman C. R. Knowles:—That concludes our report.

Vice-President John E. Armstrong:—This report barely indicates the work that this Committee is doing. It is breaking new ground. It is one of our youngest Committees and is breaking ground that should be broken. It is getting results. The Committee is excused with the thanks of the Association (Applause).

Mr. E. E. R. Tratman (Civil Engineer—by letter):—In regard to the welding of rails, the report on track welding, page 504, deals only with the building up of worn rail ends. It might be of interest to supplement this matter with information as to the welding of rail joints to form continuous rails and so reduce the work of maintaining joints. This has been done for tunnels and for wide road crossings, where joint maintenance would be troublesome. The report of the Committee on Grade Crossings, page 564, provides for welding of the latter class. On the New South Wales Government Railways, Australia, the thermit welding of rails has been practiced to eliminate a proportion of the joints, and a total length of equal to  $7\frac{1}{2}$  miles of single track has been thus welded. The greatest continuous length is said to be 225 feet, with 11/16-inch joint spaces at the ends. On the South African Government Railways, old 60-lb. rails 21 and 24 feet long, against the present standard length of 40 feet, have been welded into lengths of 63, 69 and 72 feet for use on branch lines. In England, last summer, I was shown some electrically welded rails in main tracks, making lengths of 120 feet with 60-foot rails. The welds and rails were in excellent condition after some years of service, but the work was purely experimental and seems to have been carried no further than the individual experimental joints.

## DISCUSSION ON WATERPROOFING RAILWAY STRUCTURES

(For Report, see pp. 699-712)

Mr. J. A. Lahmer (Missouri Pacific):—The report of this Committee consists of two parts, which are shown in Appendix A, page 699, Bulletin 362, on When to Waterproof or Dampproof and Methods to be Used, and Appendix B, Specifications for Membrane Waterproofing. I will ask Mr. Dalstrom, the Chairman of the Sub-Committee, to present that part of the report which is included in Appendix A.

Mr. O. F. Dalstrom (Chicago & Northwestern):—The report of the Sub-Committee on When to Waterproof or Dampproof and Methods to be Used is given in Bulletin 363, on page 699. I will summarize this report briefly. At the bottom of page 699 are two definitions that are important:

“Waterproofing.—The treatment of any material or structure to prevent the entrance or passage of water or other liquid under head.

“Dampproofing.—The treatment of any material or structure to prevent the entrance or passage of water or other liquid not under head.”

Proceeding in accordance with these definitions, the Sub-Committee prepared a set of principles, nine in number, governing the use of waterproofing or dampproofing of railway structures. These are shown on page 700 under the heading of “Waterproofing.” Seven additional principles, under “Dampproofing”, appear on pages 700 and 701. Following this are a number of specific cases, under eleven paragraphs. The specific cases enumerated are:

- Abutments, Piers and Retaining Walls.
- Single-Span Arches and Box Culverts.
- Pedestrian Subways.
- Arches—Multiple Span with Spandrel Fill.
- Precast Slabs for Bridge Decks and Floors.
- Cast-In-Place Concrete Bridge Decks or Floors.
- Pump Pits for Subways and Basements.
- Pipe Manholes and Pipe Tunnels.
- Water Containers.
- Walls and Floors of Buildings.
- Grain Elevator Pits and Similar Underground Structures.

This report is submitted as information, and comment and criticism are invited.

The President:—It will be so received.

Chairman J. A. Lahmer:—The Specifications for Membrane Waterproofing which begin on page 702 of Bulletin 363 are the same as those that were presented at the convention a year ago, except that they have been passed through the hands of an editing committee to smooth them up and eliminate inconsistencies; they are substantially the same as those of last year excepting for a few minor changes that were made for the clarification or simplification of various requirements.

It is moved that these specifications be accepted as recommended practice and be printed in the Manual in place of specifications on pp. 1171 to 1180, inclusive, of the 1929 Manual.

The President:—You have heard the motion, gentlemen. The subject is now open for discussion. In order to give opportunity for discussion of each article in these specifications, I will ask the Chairman to read them by caption and hesitate a moment to permit discussion.

(Sub-headings of various sections were then read by the Chairman.)

The President:—Is there any discussion on the motion to adopt this specification as recommended practice and for printing in the Manual? All those in favor will say "aye"; contrary-minded. It is carried and so ordered.

Chairman J. A. Lahmer:—That is all.

The President:—This Committee, I feel, has presented a very valuable report which represents a lot of study on the specifications for membrane waterproofing and will be of considerable value to the railroads. They are now dismissed with the thanks of the Association (Applause).

## DISCUSSION ON RAIL

(For Report, see pp. 829-878)

Mr. Earl Stimson (Baltimore & Ohio):—We begin the report by a presentation of the rail statistics by Mr. Barnes, Engineer of Tests of this Committee.

Mr. W. C. Barnes (Engineer of Tests, Rail Committee):—The rail failure statistics for 1932 will be found on page 832 of Bulletin 363. These statistics are presented in the usual manner, and I believe they are fully self-explanatory.

I might call particular attention to Fig. 5 on page 836, which shows the rates of failure of rollings from 1927 to 1931 separately by mills. I think this is particularly interesting because the variation in the performance of the different rollings from any one mill is quite pronounced. I think it will be sufficient to move that these rail failure statistics be accepted as information.

The President:—A motion is unnecessary. They will be accepted as information and printed in the Proceedings, unless there is objection thereto. Would anyone like to ask Mr. Barnes any questions on these statistics?

Mr. W. C. Barnes:—Transverse fissure statistics will be found on page 845. These statistics give a cumulative total of failures reported up to December 31, 1932, from all roads. The total number of fissures included in these statistics now amounts to 65,281 fissured rails.

During the last year the service failures, that is, those that actually failed in service, totaled 4,624, and those that were detected and, hence, removed before actual failure totaled 2,430. That seems a very large total, but it is a great deal better than we have had in preceding years.

Exclusive of the detected fissured rails, the failures in 1932 were at the rate of 12.7 per day, which rate, however, has declined from a high of 16 per day in 1929, and indications are that the reduction in number will continue.

Table 3 on page 853 shows a great variation in the fissure record in the rollings of the different mills. These statistics are presented as information.

The President:—They will be received as such. Are there any questions, or is there any discussion on this subject of transverse fissure statistics?

Mr. W. C. Barnes:—On page 854 there is a short summary of the operating results of the A.R.A. rail fissure detector car. On November 14 the car completed its fifth year of operation under the direction of the Rail Committee, having traveled on its own wheels a total of 50,000 miles and tested 23,181 track miles of rail in all sections of the country. Approximately 6,600 track miles were tested during the last year. This work has been done without any interruption whatever, the car having been in rental service continuously except for the short periods necessary for shopping.

Many improvements have been made in methods. The mileage per day has been increased, and the efficiency has also been increased.

The American Railway Association recently approved the purchase of a substantial car to house the detecting equipment, which car is under construction and will be a great improvement, as the other car was rather weak in the knees.

This report is also submitted as information.

The President:—It will be received as such. Are there any questions?

Mr. W. C. Barnes:—The other report I have to present will be found on page 859, tests of alloy and heat treated carbon steel rails. This is simply a compilation of statistics of the purchase of these rails and reports of service tests from various roads that have installed them. During the last one or two years very few of these rails have been purchased on account of conditions, and the statistics are presented simply to keep our record up to date. They are too long to read. They are presented as information.

The President:—They will be so received. Is there any question you would like to ask Mr. Barnes on this subject?

Chairman Earl Stimson:—Subject (4), cause and prevention of rail battering, and Subject (9), heat treating of rail ends to reduce wear, will be found in Appendix F, page 854. The report will be presented by Mr. Graham.

(Mr. F. M. Graham read Appendix F found on page 854 of Bulletin 363.)

Mr. F. M. Graham (Pennsylvania):—The Committee makes the following recommendations:

"In view of the satisfactory experience of heat treating rail ends on the C.M.St.P.&P., C.&O., Erie Railroad, and Pennsylvania Railroad, also considerable experimental testing on several other roads, where results have been most encouraging, it is recommended that the heat treating of rail ends be generally followed in the case of new rail, cropped rail, or where rail batter has not progressed to an objectionable extent.

"It is further recommended in connection with the above that where necessary the top of rail ends be ground to the same height.

"Some of the above-mentioned methods of heat treating rail ends have only been available for a short time, and their relative merits and costs are not now known and should be further studied.

"It is urged that extensive tests by railroads generally of the practice of heat treating rail ends be undertaken and that information including results and costs by various methods be made available."

The President:—While this report is submitted as information, it is a very important subject and a live one at this time. I am sure the Committee will welcome discussion of the subject.

Chairman Earl Stimson:—Further subjects that your Committee considered are economic value of different sizes of rail—again we report progress on this subject; rail lengths in excess of thirty-nine feet—the report on this subject will be found in Appendix H, page 858. This report is offered as information. The Committee does not consider the time opportune to increase the length of rail, so we make no recommendations.

Subject (8), redesign rail sections heavier than 100-lb. At the last convention the Committee offered, and the Association adopted, the 131-lb. rail section. Immediately after the convention, work was started on a rail section to take the place of the 110-lb. A section was finally submitted to the Association by a letter-ballot and was adopted by a very large majority.

In connection with the adoption of these two new sections, the 110, 120, 130, 140 and 150-lb. sections that were in the Manual were withdrawn, so that the standard rail sections are now the 90-lb. RA-A, the 100-lb. RE, the 112-lb. RE and the 131-lb. RE.

The next assignment of the Rail Committee is that of designing joint bars to go with the new sections of rail. This is quite a live subject; in fact, it is hotly alive. The

Committee went right to work on it. As a result there was presented for letter-ballot in January the joint bar and assembly for the 112-lb. RE rail. This is given in Appendix K. This joint bar and assembly was adopted by the Association by a vote of about three to one.

The Committee made the 131-lb. joint bar and assembly the subject of a supplemental report which was issued on March 5, in which the adoption of the joint bar section and assembly as standard is recommended. Within the past two days a question has been raised, the settlement of which is desirable before action on the adoption of the 131-lb. joint bar section is taken by the Association.

While the Committee feels confident that the outcome of the matter will be satisfactory, we consider the proper course to take is to withdraw, for the time being, the recommendation to adopt the joint bar section.

The other recommendations connected with the joint bar and assembly, such as the punching of the bars, the drilling of the rail, the lengths of the bars, the details of the bolt, should be acted upon at this time.

Referring to the supplement to the Rail Committee report offering the 131-lb. joint bar, the first recommendation shown on the second page, the adoption of the 131-lb. RE joint bar section is withdrawn. We will present it at some later time.

The second recommendation, "Change height of bolt hole above base of rail for the 131-lb. RE rail section adopted by the Association in 1933 from 3-1/4 in. to 3-3/32 in." is recommended, and I move that it be adopted.

I might say that these changes are in line with the recommendations for rail drilling and joint bar punching made by the Coordinator of Transportation last fall to be used with the 112-lb. and 131-lb. rail sections, so they are practically established now, but have never been acted upon by the Association for the 131-lb. rail. This spacing has been adopted for the 112-lb. rail by the letter-ballot on the 112-lb. joint bar.

The President:—The motion before the convention is Recommendation No. 2, to change the height of the bolt hole above the base of the rail. Is there any discussion? Are you ready for the question? All those in favor will signify by saying "aye"; contrary-minded. It is carried.

Chairman Earl Stimson:—The third recommendation: "Adopt the 24 in. and 36 in. joint bar bolt hole spacing shown on the print of the 131-lb. RE rail joint and assembly, dated February 19, 1934, which accompanies the report." I move its adoption.

The President:—It has been moved and seconded to adopt the 24 in. and 36 in. joint bar hole punching. Is there any discussion? All those in favor will vote "aye"; contrary-minded. It is carried.

Chairman Earl Stimson:—Recommendation No. 4: "Adopt the rail drilling for the 131-lb. RE rail section shown on this print"

I move its adoption.

The President:—It has been moved and seconded that we adopt the rail drilling for the 131-lb. rail. Is there any discussion on this question? All those in favor will signify by saying "aye"; contrary. It is carried and so ordered.

Chairman Earl Stimson:—The fifth recommendation: "Adopt as a whole the plan for assembly for the 131-lb. RE rail." This omits the rail joint section but covers all the rest of the details—the bolt hole spacing, the drilling of the rail, the punching in the bar, and the bolt and nut. I move the adoption of this recommendation.

The President:—It has been moved and seconded that we adopt the assembly for the 131-lb. RE rail. That is Recommendation No. 5, with the words "joint bar and" omitted. Is there any discussion on this motion? All those in favor will vote "aye"; contrary. It is carried and so ordered.

Chairman Earl Stimson:—We now come to the Revision of Manual, Appendix A, which will be presented by Mr. Blaess.

Mr. A. F. Blaess (Illinois Central):—Revision of Manual will be found on pages 830 and 831 of Bulletin 363.

"The following changes and additions of Definitions beginning at page 135 of the Manual, are recommended:

"Add note after definition for Alloy Steel:

"The above definitions for iron and steel apply to joint bars, bolts and spring washers as well as rail."

"Insert in alphabetical order under heading Manufacture, the following additional definition:

"Cobble.—In a rolling mill, any steel which has become bent or twisted so that it cannot be finished by rolling is termed a 'Cobble'.

"Hotbed.—A series of skids on which rails are placed for cooling after rolling, cambering and sawing."

Substitute for the present definition of Crop End, the following:

"Crop End.—A piece cut from the end of a bloom or rail during manufacture."

The next is merely a correction. "Remove the word 'with' in definition of Compound Fissure, line 2, page 16 of 1932 Supplement to Manual, Bulletin 347."

I move the adoption of the change and the addition to the definitions just read under the heading of "Definitions" for publication in the Manual.

The President:—The adoption of the definitions has been moved and seconded. Is there any discussion on this subject? All those in favor say "aye"; contrary. It is carried.

Mr. A. F. Blaess:—Under the heading of Rail Specifications the following corrections or changes are recommended:

"Section 6, page 149: A request having been received for height of drop to be used in applying drop test to 70-80-lb. rail, the following addition is recommended:

"For 70-80-lb. rail inclusive.....17 ft."

I might add that this is in accordance with A.S.T.M. standards.

"Section 12, page 150: Add 'or drawings' after word 'templates' in line 2.

"Substitute: 'width' for word 'length', line 4.

"Section 20 C, page 152: In order to avoid payment for weight in excess of the one-half of one per cent overrun allowed in Section 13, it is recommended that the words 'subject to limitation of Section 13' be added making this subsection read—

"Rail accepted will be paid for according to actual weight subject to the limitations of Section 13."

I move the adoption of these changes and additions for publication in the Manual.

The President:—You have heard the motion. Are there any recommended changes on the rail specifications? All in favor vote "aye"; contrary "no." It is carried.

Mr. A. F. Blaess:—Under the heading "Drilling of Rails" the following corrections or changes are recommended:

"(1) Paragraph 1, page 162: Elimination of this general recommendation as unnecessary and inadvisable, as specific directions for drilling are elsewhere given. This includes the necessary renumbering of the succeeding paragraphs.

"(2) Page 162: Revise data under heading 'Application of Recommended Rail Drilling to Standard Rail Sections,' to include only the present standard sections, as follows:

| Weight of<br>Rail, Lb. | Type of<br>Rail | Height of Bolt Hole<br>Above Base of Rail,<br>Inches |
|------------------------|-----------------|------------------------------------------------------|
| 90                     | RA-A            | 2-37/64                                              |
| 100                    | RE              | 2-45/64                                              |
| 112                    | RE              | 2-7/8                                                |
| 131                    | RE              | 3-3/32                                               |

"This eliminates sections which are no longer standard and adds data for the 112-lb. and 131-lb. RE sections.

"(3) Page 162: Revise the sentence, 'The standard drilling for rails should be as shown in the following diagrams' to read, 'The standard drilling for standard rails up to and including 100 lb. per yard should be as shown in the following diagrams.'"

I move the adoption of these changes and additions as shown under the heading "Drilling of Rails" for publication in the Manual.

The President:—It has been moved and seconded that we adopt for publication in the Manual this drilling of rails. Is there any discussion on this subject? All those in favor will signify by saying "aye"; contrary. It is carried.

Mr. A. F. Blaess:—Under "Specifications for High Carbon Steel and for Quenched Carbon Steel Joint Bars" (1929 Manual, pages 166-169):

"In order to keep the same terms in all Rail Committee specifications, substitution of the word 'heat' for 'melt' wherever the latter is used is recommended.

"While title of these specifications refers to joint bars, there are a number of references to splice bars on page 169. Recommend uniform use of the term 'joint bars.'

"Paragraph 13, page 169, last line: Recommend quenching temperature be shown in degrees Fahr. and degrees Centigrade enclosed in parentheses."

I move the adoption of those changes for publication in the Manual.

The President:—There has been moved and seconded the adoption in the change of Specifications for High Carbon Steel and for Quenched Carbon Steel Joint Bars. Is there any discussion on this subject? All those in favor will vote "aye"; contrary. It is carried and so ordered.

Mr. A. F. Blaess:—Under the heading "Revision of Form 402 A":

"Following changes are recommended, pages 180-181 of Manual: Face of form, item 38—Change 'Horizontal Fissure' to 'Horizontal Split Head.'

"Back of form—Under 'Description of Rail Failures', add new definition 1 B as given on page 16, Bulletin 347: (B) 'Compound Fissure—A horizontal split head which in developing extends into a plane other than horizontal'.

"Designate definition for 'Ordinary Break' by (C) instead of (B) and in third line of same substitute word 'compound' for word 'horizontal'.

"4. 'Split Head'—Change title to 'Vertical Split Head'.

"Add a new definition 5 as given on page 16, Bulletin 347: 'Horizontal Split Head'—'A horizontal progressive fracture originating in the interior of the head of rail usually indicated on the side of head by longitudinal seam or crack and flow of metal.'

"Renumber definitions 5, 6 and 7 as 6, 7 and 8.

"Eliminate the word 'Internal' under the cut of 'Internal Transverse Fissure'."

I move the adoption of these changes in the Manual.

The President:—It has been moved and seconded that we adopt the changes recommended in the Revision of Form 402 A. Is there any discussion on this subject? All those in favor of this motion will vote "aye"; contrary. It is carried.

Chairman Earl Stimson:—The rail investigation to determine the causes of transverse fissures and their remedy, that is being carried on at the University of Illinois, has progressed as per schedule. I know you are all very anxious to learn what has been done. Prof. H. F. Moore, who has charge of that work, has kindly consented to be with us this evening and tell us the story.

Prof. Moore, we will be glad to hear from you now.

(Prof. Moore described the experimental work carried on at the University of Illinois, and illustrated his remarks by lantern slides.)

The President:—That concludes the report of the Rail Committee. This Committee has had very important assignments. It keeps us posted on developments in the rail

problem. They have had a very difficult assignment this year, that of preparing plans for rail joints. We appreciate the work they have done, and now we will excuse them with the thanks of the Association for their good work (Applause).

Mr. E. E. R. Tratman, Civil Engineer—(by letter):—With reference to the proposed standard joint bars or splice bars and joint assembly for the new 112-lb. rail section, it is disappointing to find that the call for ballot votes gives no information on the basis of the design, either as to the form of cross-section of the bars or as to the bolt spacing of  $5\frac{1}{8}$ -inch and  $6\frac{1}{2}$ -inch, which differs from the uniform spacing of  $5\frac{1}{2}$ -inch now recommended in the Manual. Thus there is nothing to guide or inform in the casting of the ballot. Apparently the section of the splice bars is such that the rail cannot be held down by spike heads on the joint ties, the spikes being reversed so that they only prevent lateral motion. It would seem somewhat undesirable to adopt a type of rail joint as the Association's standard without further knowledge of the basis of its design, or opportunity for adequate examination and discussion of the design.

## DISCUSSION ON STRESSES IN RAILROAD TRACK

(For Report, see Bulletin 358)

Dr. A. N. Talbot (University of Illinois):—The Sixth Progress Report is printed in Bulletin 358. As it contains 240 pages and includes many tables and diagrams, I shall not attempt to read it or even to make a digest of it. Let me say concerning this report that time and thought were given to its writing to make it clear and explicit, without being too bulky. At best, it is not easy reading, not a primer, not a novel. It will require careful reading and some study. I hope it will repay study to those who are interested in the topics discussed.

The field taken up in this report is much the same as that of the Fifth Report—(1) the rail-joint, and (2) variability in the structure of the track and the need for greater uniformity. Last year and the year before I talked on some of the matters which have been included in the Sixth Report. It does not seem necessary now to go over the same ground.

I want, however, to state again some of the relations between the size of rail, the stiffness of the substructure (using the term "substructure" here to represent the ties, ballast and roadbed—in other words the rail support), the depression of the rail all along its length, and the distribution of tie pressure reactions, which may not generally be accepted or fully understood.

**Relation of Tie Pressure to Size of Rail and Stiffness of Sub-Structure.**—First, let me remind you that for track with small irregularities of play between rail and tie and tie and ballast bed, the loads or pressures on individual ties for a given track are proportional to the depression or lowering given to the rail by the wheel loads.

In the reports of the Committee, the term "modulus of elasticity of rail support  $u$ " has been used to express the relation between the magnitude of a load applied all along the rail and the magnitude of the resulting depression or vertical movement of the rail, it thus being a measure of the stiffness of the rail support or substructure below the rail.

The analysis of track as an elastic structure (checked by tests) shows that the rail depression for a group of closely spaced wheels varies only slightly with the size of the rail, whether 90 or 130-lb. per yd. Take the depression of the main driving wheel, it does not differ far from being inversely proportional to the modulus of elasticity of the rail support used, regardless of the weight of the rail. The values for the other drivers are similarly nearly inversely proportional to this modulus. The weight on the drivers is evidently supported by about the same length of track, and the average depression

of rail along this length of wheelbase does not vary greatly, regardless of rail stiffness, and this average depression is nearly inversely proportional to the modulus. Take, for example, a modulus of 1500 which is average track, and 3000 which is much stiffer track. The depression of the first track will be twice that of the second track, and the vertical movement of rail, tie and ballast is double. For the wheels of two trucks of two coupled cars, which is another condition involving high pressures, as well as high stresses, similar relations are found.

Since the intensity of rail pressure on a tie is proportional to the rail depression and to the modulus  $u$ , it follows that upward pressure against the rail at the main driver is nearly the same for any rail section and any rail-support stiffness. This, I think, has not usually been so accepted. For other driving wheels than the main driver, the relation existing between intensity of pressure and rail section and the modulus  $u$  does not vary greatly from uniformity. In other words, the pressure of rail on individual ties at or near the main driver (and to nearly the same extent at the other drivers) differs little for the several weights of rail and for the range of values of the modulus  $u$ . This fact may well be kept in mind in considering the loads coming on ties and ballast.

Verification of these statements may be seen by reference to Fig. 91 and 92 and the nearby text of the Sixth Report. Fig. 91 shows the vertical movement of the rail for a Mikado locomotive; these distances are proportional to the magnitude of the tie pressure for a given modulus  $u$ . Fig. 92 shows similar relations for the four wheels of two coupled cars on one rail. It will be found that the maximum tie pressure at a wheel of the two trucks of two coupled coal cars will not differ much for the different rails for different values of the modulus. For long trains of heavy cars the tie loads of these coupled trucks become an influential factor in producing deterioration of track surface. It may be expected, then, that the average tie pressure within a group of closely spaced wheels, whether for locomotive or coupled cars, will not differ greatly through the usual range of rail weights and rail-support stiffness.

Assuming, then, that the average tie pressure throughout the length of a given group of wheels due to given wheel loads is approximately independent of the rail section, and, likewise, independent of the stiffness of the rail support, attention may be directed to the vertical movement of the rail support when this group of wheels moves along the track.

**Effect of Up-and-Down Movement.**—The vertical movement of the rail (rail depression) at one of the four wheels of the trucks of two coupled cars, as the wheel loads are applied, for our comparison may be taken at about 0.25 in. for a modulus of 1500, and 0.10 in. for a modulus of 4,000. This means that the rail and the top of the tie will move downward, for the less stiff support, say, two and one-half times as far as they do for the stiffer support. The downward movement within the ballast under the tie will have a somewhat similar ratio of movements. All the movements are followed by a corresponding rise when the wheels have moved on.

This up-and-down motion under application and release of pressure to the tie every time a group of coupled trucks moves by (with approximately the same magnitude of tie pressure, whether the vertical movement be 0.25 in. or 0.10 in.) is a form of repetitive loading which, of course, has its effect on the stability of the structure and on the constancy and duration of good line and surface and on the ability of the ballast itself to continue to fully resist the load.

It is apparent that the effect of repetition will vary in some way with the magnitude of this vertical movement, and that the energy applied by a group of wheels will vary with the amount of the vertical movement. With 100 or 150 heavily loaded cars the

repetitive up-and-down movement of the ties and ballast at every group of car wheels puts a repetitive loading of high magnitude on the track substructure.

**Value of Stiffness of Substructure.**—All this has a bearing upon the value of increased stiffness in the tie and ballast substructure and upon the condition of the substructure. Although quantitative relations are not known, it is to be expected that the less stiff track (for example, that with a vertical movement of 0.25 in. as compared with 0.10 in.) will be put out of form with the passage of much less traffic, especially if the track is variable in condition from point to point and tie to tie. And of course the nature and depth of the ballast material and its consolidation and stiffness, as well as the quality of the tie structure, will largely determine the stiffness and depression of the substructure.

Such a finding is only a restatement of common knowledge, that a substantial substructure having deep, consolidated ballast on a solid roadbed will carry a much greater amount of traffic without maintenance work than will a less stiff substructure. It should be accepted that a stiff substructure has a real value in carrying heavy traffic. I do feel that the quality of substructure should not be overlooked when we are talking about weight of rail and other track matters.

**Value of Uniformity of Track.**—Last year I spoke of the ill effects of variability in track, variability from tie to tie and from point to point along the track. I want to ask again: Is not the search for methods and means of getting reasonable uniformity worth while?

**Value of Heavier Rails.**—The greater stiffness of the heavier rail sections has frequently been considered of value as carrying the load farther ahead or behind the wheel and of decreasing the load on individual ties. As has been seen from the relative rail depressions the greater stiffness of the heavier rail does not correspondingly affect the springiness or resilience of the track in taking sudden changes of load applied through defective rolling stock or by abnormal dynamic augment of an imperfect counterbalance. It is the stiffness of the substructure that mostly governs the springiness of track under a group of wheels, though the stiffness of the rail will take a local part in the spring, particularly when the increased load is on only one wheel as with the dynamic augment of the main driving wheel. However, other advantages which come with the added stiffness of rail give value to the heavier section.

Under the heading of stability of rail in the Sixth Report the following statement may be found: The greatest value of the heavier rail may be said to be the greater stability it gives to track. Stability implies the ability to maintain favorable conditions, to resist unusual or unexpected forces or loads, to overcome the variations. The greater stiffness of a heavier section aids in carrying loads over imperfectly tamped track and irregular supports; it resists lateral thrusts and lurches without undue distortion of alignment; it aids in maintaining proper surface. Even the added mass of the heavier rail gives an element of stability. The added stiffness should be considered a help in reducing the costs of maintenance.

It may be added that the value of the increased size of rail will depend upon many circumstances, among them amount and nature of traffic, nature of substructure, wheel loads and speeds, and any economies involved in the situation. It can hardly be expected, however, that this value may be expressed quantitatively in formulas and equations, but studies of accompanying conditions should be helpful in forming a judgment.

**Lateral Strength and Stiffness of Joint Bars.**—Questions have been asked in the Rail Committee about the lateral stiffness and strength of certain sections of joint bars. To what extent the bars and rail in any rail-joint act integrally in resisting lateral forces depends upon the fit between bar and rail and upon the bolt tension.

To the question raised concerning the comparative lateral strength of the angle bar joint used with the 127-lb. rail of the New York Central Railroad and a joint with study section G for 131-lb. rail described in the Sixth Report the answer was made that from the tests and analyses on rail-joints, assuming proper fit and bolts tight or moderately tight in both cases, the effective lateral strength of the joint having study section G bars would be more than 50 per cent greater than that of the New York Central angle bar joint. Possibly the advantage might be nearly double. Reference is here made to a lateral load within allowable bending and distortion in track—no attempt was made to find ultimate carrying load. With low bolt tension there would be much less difference, and neither would do well.

The foregoing applies to both tangent track and curves. On the sharper curves the greatly increased lateral forces may tax any form of rail-joint.

It should be said that the G section referred to is somewhat heavier and stronger than the section for 131-lb. rail reported by the Committee on Rail.

**Tests and Inspection of Worn Joint Bars.**—The staff has started laboratory work on worn joints to find the characteristics of their action under various conditions. Inspection tests have been started on track having built-up bars in the joints. This work will be continued.

**Counterbalance Calculations.**—Counterbalance of locomotive driving wheels continues to be of interest. That topic has been assigned by the Committee on Outline of Work and the American Railway Association. Cooperation with the Mechanical Division is planned. Little opportunity has been found beyond what was done several years ago. It seems well, however, to present some comparisons of counterbalancing for locomotives of the old Santa Fe type, with small driving wheels, diameter 63 in., rather difficult to counterbalance, as an example of what has been done by one railroad.

A locomotive similar in design to one used in tests we made on track more than fifteen years ago has recently been modified by equipping it with a new form of main driver, a double disc wheel, which permits the placing of a much heavier counterweight, 1,000-lb. A comparison will be made first of the calculated rail stresses for the old locomotive and the modified locomotive and second of the rail depressions of the two locomotives. In the calculations, following the practice of mechanical departments, for the purpose of a comparison a diameter speed has been used, 63 miles per hour, a speed higher than these locomotives should be run.

Fig. 1 gives the stress in rail at various places along the locomotive. The upper diagram shows by the vertical ordinates the calculated stresses in the rail at and between

Fig. 1 Rail Stress and Counterbalance

wheels for the old counterbalance on the locomotive that was tested. The heavy line shows values with the counterweight up. The magnitude reaches 50,000-lb. per sq. in. at the peak for the main driver. The dotted line gives the stresses for counterweight down. The effect is seen to be different. The counterweight on the main driver was very much smaller than what it should be, though as large as there was room for. The locomotive was far from being balanced.

The lower diagram shows the stresses for a similar locomotive, not on the same railroad, on which has recently been installed a new form of main driving wheel that gives opportunity for providing an adequate counterweight. In some ways the two locomotives are not the same, but the comparison is a fair one.

The counterweight of 1000-lb. on the main driving wheel has reduced the maximum stress considerably, though it should be said that in the change the main drivers were cross-counterbalanced. However, attention is called to another difference—the upper locomotive had comparatively little counterbalance for the reciprocating parts, and the counterbalance of the lower locomotive follows the regulations of the Mechanical Division in taking one-half of the weight of the reciprocating parts and counterbalancing for this amount. This desired counterweight has been divided among the four drivers, other than the main driver. It is a pertinent question whether so large a proportion of the reciprocating parts is necessary in the counterbalancing.

Fig. 2 deals with rail depressions. Bear in mind that these rail depressions are proportional to the tie pressures, practically so. The line for static loading is shown. The heavy line represents the counterweight up. For the locomotive with the old counterbalance the depression under the main driver is 0.68 in.; under the end drivers the depression is only about 0.1 in. Correspondingly, the load on the ties under the main driving wheel would be more than six times as great as under the end drivers. For the counterweight down there is a somewhat similar form of curve, showing the great variation in tie pressures and in depression of the rail.

Fig. 2 Rail Depression and Counterbalance

The middle diagram shows the rail depressions for the locomotive with the new main wheel and new counterbalance. It will be seen that the depression under the main driver is about the same regardless of the position of the counterweight, and this condition exists with no extra counterweight applied to this wheel to balance any of the reciprocating parts. For this locomotive half of the weight of the reciprocating parts was counterbalanced by dividing it among the other four drivers. For these four drivers

there is a great difference between the depression for counterweight up and counterweight down.

The lower diagram shows what would have happened if the proportion of the reciprocating parts used in counterbalancing the old locomotive had been applied to the present locomotive. In this case the depressions and, therefore, the tie pressures will not vary very much as the train runs along the track, which, of course, is a much more favorable condition.

A somewhat similar comparison might be made on the effect of imperfect counterbalance on bridges. It may be said further, that in a variety of ways the design and condition of rolling stock affects the maintenance of the track, and, likewise, the design and the condition of the track affects the operation and maintenance of both locomotive and cars. This interrelation is worthy of a more extended study.

**Pere Marquette Concrete Roadbed.**—Last fall a brief test, lasting two weeks, on the stretch of track of the Pere Marquette Railroad having a concrete roadbed was conducted with a view of learning something of the action of this type of roadbed. Although the data have not been finally worked up, it may be of interest to report some of the results. Tests were made on the two forms of construction. In the older one built several years ago, the rather thick rectangular slab rises to the level of the rail. The newer one has a lighter base slab and two longitudinal supporting members continuous with the base, one under each rail, and having cross braces between these members. I will not describe the form of the roadbed nor the method of fastening the rail to the slab. Many of you are familiar with the construction.

What will be of interest is the magnitude of the stresses in rail and their approach to uniformity, and also the amount of the rail depression and the distribution of the reaction pressures on the rail. The older stretch of track has the rail laid on a thin strip of composition material, insulating fiber, which rests directly on the concrete. This strip is about  $\frac{1}{8}$ -inch thick, the width of the rail base, and rather hard. For the newer form the rail base rests on a  $\frac{7}{8}$ -inch creosoted pine board, a little narrower than the rail base, and this rests in a shallow groove in the concrete. The general appearance is shown in Fig. 3. The space between the longitudinal members, a few inches deep, is filled with ballast.

*Fig. 3 Pere Marquette Concrete Roadbed.*

In the test a static load was used, a 30,000-lb. wheel load on each of the four wheels of one truck of a coal car—a very heavy load of course. Calculations for the conditions of the good second tie-and-ballast track alongside the concrete roadway indicated a mean stress in base of rail of 15,000-lb. per sq. in. with the given test load. In the newer stretch, the one in the picture, the average of the stresses in base of rail found at 78 spots was 6,800-lb. per sq. in., a little under half of that calculated for the tie-and-ballast track. On the older stretch, at 33 spots, the average stress in base of rail was 3,800-lb. per sq. in., about one-quarter of that calculated value for the tie-and-ballast track. The difference in the value of the stresses in the two stretches of concrete roadway is due principally to the greater compressibility of the wooden strip used as a rail support in the new stretch over that of the thinner and harder strip in the older stretch.

Let me say that less variation in stress from point to point was found as compared with tie-and-ballast track. The board is a better support than the thin, hard insulating fiber. It takes up the variations and has some elastic action. As is to be expected, the slabs gave a good account of themselves. The depression of the slabs under the load averaged .06-inch for the newer slab and .04-inch for the older slab. In addition to the depression of the slab, the rail has a further depression which averaged .09-inch on the newer slab and .05-inch on the older slab, making .15-inch and .09-inch in all. This additional depression is made up of the compression of the wood and the play. Variations in play found between rail and supporting strip and concrete contributed to the variations in depression and stress found in the tests.

It may be remarked that the way of supporting the rail on the slab is of importance and to some extent is experimental. In these tests the results showed very fair uniformity of stress and depression and a much stiffer roadbed than the usual type of construction.

**Bearing Between Rail and Tie-Plate under Load.**—This afternoon in the discussion of the report of the Committee on Track I referred to calculations to show the position of the bearing between the rail base and the tie-plate under load.

Analyses were made on several assumptions of the position and manner of the bearing between rail base and tie-plate. Calculations were made of the curves of flexure of both rail base and tie-plate when supported by the compressible wood of the tie. The consistency or inconsistency of the deflections of rail base and tie-plate under load were studied. In Fig. 4 are given flexural curves for rail base and tie-plate for a central load on the rail with an assumed distribution of the tie reactions shown at *A*. Several plausible assumptions for the position of the bearings between rail base and tie-plate were dismissed as impossible after comparison of the curves of flexure found. Then the assumption was tried that one of the resultants of the reactions between rail base and plate is located  $\frac{1}{4}$ -inch within one edge of the base and the other at  $\frac{1}{4}$ -inch within the other edge. The curves of flexure at *C* in the figure show that this assumption gives contact between rail and plate only at the middle of the width (the rail flanges curling up from the plate), a result wholly inconsistent with the assumption. Assuming that the resultants of the reactions between base and plate are located at  $\frac{3}{4}$ -inch from edge of base, the curves of flexure

Fig. 4 Flexure of Rail Flange and Tie-Plate

were found to be as shown at *B*. These curves show no contact between base and plate through the middle portion and indicate that the reaction resultants are somewhat outside of the  $\frac{3}{4}$ -inch point. Further computation for resultants at  $\frac{1}{2}$ -inch inside the edges of base gave curves of flexure that are consistent with the assumption used.

Other calculations were made for loads applied away from the middle of the head, and varying farther from the vertical direction, and with other dimensions of the tie-plate. It was concluded that a point  $\frac{1}{2}$ -inch inside the rail edge would be a suitable position to consider as the position of the reaction resultant in calculations for the stresses developed in rail flanges and tie-plates. It is true of course for wheel loads applied in a way that gives a very large lateral thrust, or for tie bearings that produce similar large lateral forces, that the resultant may be so inclined as to act through one edge of the rail base (and only one) and thus that a much higher flange stress will be developed.

The deflections of the curves of flexure found are very small, but they fix the bearing contacts when the rail base and the tie-plate have plane surfaces that are in contact in an unloaded condition. If the surfaces are convex to each other when unloaded, the rail will rock under an applied load. If the surfaces are concave to each other the bearings under load will be nearer the edge of the rail base than was reported above. If the surfaces are irregular a position nearer the edge should be assumed. In general a position of the reaction resultant a half-inch or less from the rail edge may properly be made the basis of strength calculations.

**Long Length of Continuous Rail.**—In conclusion I want to refer to a piece of track, not tested by us, where an interesting experiment is in progress on a long length of continuous rail. Reports from Germany on long stretches welded into continuous rail have been of interest. The practicability of long lengths of rail is, of course, largely a matter of time tests. Although the Committee has had no part in planning this, it seems well to call attention to one of the longest stretches of rail in this country.

Last August the Delaware and Hudson Company at Albany, New York, laid 130-lb. rail and welded it in continuous stretches of 2,800 ft., 2,300 ft. and 500 ft., partly on curves. The track is a very substantial structure in every way. Mr. Clarke, the Engineer of Maintenance of Way, says that inspection and measurements will be made on this track to learn its behavior.

Here is one opportunity to get information on whether, in our northern climate, the matter of changes of temperature and other influences, together with need for maintaining and repairing track during hot weather, will interfere with the satisfactory use of such long rails. The results should be of interest and value. Mr. Clarke has extended an invitation to the Committee to make such inspection and test as may be desired.

I understand that other railroads have made similar installations.

The President:—I am sure we all realize the importance of this very difficult research work that is being carried on by Dr. Talbot and his Committee. I wish, however, to mention to the various Committees the importance of their application of the knowledge obtained from this research work in the study of their particular problems. It is of inestimable value to many of our Committees, such as Ballast, Ties, Track, and others, and they will do well to study Dr. Talbot's reports. They will find information that will help them very much.

Dr. Talbot, on behalf of the Association the Chair desires to express appreciation to you and your Committee for your very excellent work (Applause).

## DISCUSSION ON TIES

(For Report, see pp. 779-828)

Mr. W. J. Burton (Missouri Pacific):—The report is contained in Bulletin 363. We will start with Appendix B on page 782. This subject is one which the Committee has had for a number of years. I will ask Mr. Foley, Chairman of the Sub-Committee, to make the presentation.

Mr. John Foley (Pennsylvania):—Appendix B is on page 782. The adherence to specifications for ties by railroads in general and the increased belief in standards for ties by the manufacturers of them is exceedingly gratifying to those of us who take a special interest in that phase of railroad maintenance.

The Committee each year becomes more and more convinced that wherever substandard ties are produced in any quantity, the reason lies in laxity of inspection by railroads. The only possible excuse there is for accepting substandard ties lies in an attempt to cover up a substandard price.

Should code prices go into effect, there would be no excuse for any railroad to accept substandard ties. Consequently, this report is submitted as an admonition as well as information.

The President:—This report will be received as information. If there is anyone who would like to ask Mr. Foley any questions, we will be glad to have him do so.

Chairman W. J. Burton:—The next subject is also one which the Committee has had for a great many years. In fact, the subject of substitute ties was one of the very first to be assigned when the Association was first organized. The Chairman of this Sub-Committee is not here today. However, there is nothing of any particular novelty. The report merely contains the record for the year, in the same form as used previously.

The next subject is reported briefly on page 787, Tie Renewals Averages per Mile Maintained. This report is a compilation of tie renewal statistics obtained from reports made to the Interstate Commerce Commission by the different railroads. Previous to this year the report has not been available until the publication of the Bulletin containing the full Tie Committee report late in the year. Last year there was considerable demand for these statistics earlier, and it was therefore arranged to publish them in the June Bulletin. The demand for these statistics seems to be so great that they ought to be published as early as possible, and the Committee will therefore continue to publish them as soon as they are made available.

Last year, at the time the United States statistics were published, the data from the Canadian railroads had not been received. We are hoping to have the Canadian data on hand this year so that it can be published at the same time as the United States data. The figures in Bulletin 363, beginning on page 788, are for the three principal Canadian railroads and in the same form as the report for the United States railroads, published in Bulletin 356.

The next subject, Recommend Standard Spacing of Spike Holes for Ties Pre-adzed and Bored for Standard Rail Sections 90-lb. to 131-lb., inclusive, will be reported by the Chairman of the Sub-Committee, Mr. Chapman.

Mr. E. E. Chapman (Santa Fe):—In 1933 the Railway Tie Association presented a request to the American Railway Engineering Association that consideration be given to the standardizing of track and its parts for the more important rail sections as to

result in standardized adzing and boring of ties. In this they presented the advantages to the tie producer and to the railroad. Those of the tie producer were:

The regular and fairly uniform production of cross-ties; the standardization of ties in their treatment, which enables the manufacturer to be reasonably sure of the sale if his ties meet specifications; the growing practice of pre-adzing and pre-boring of ties which has taken away a part of the benefit of the present standard specification of ties because of the great variation in arrangement and spacing of spike holes.

The wood preserving plants are also greatly benefited by having uniform production; the reduction in templets, knives and bits, and patterns necessary to carry through standardization reduces their cost and makes the sale of the product more sure.

They also presented the advantages to the railroad, which, on final analysis, could be obtained more in the sections which are at present being designed for rails and their fasteners.

They also presented the questionnaire which they had sent out to the various railroads and the answers. These were analyzed, and the results show a lack of agreement, and in Exhibit B for 110 and 130-lb. rails on page 797 this is brought out clearly.

There are only about ten railroads in the United States which own their own creosoting plants. Therefore, the standardization of boring and adzing of ties is important to most railroads and to a large part of tie treating industry.

A table has been prepared showing what may possibly be accomplished if the recommended standards of the Manual are followed. If the standards were adhered to it would be possible to adze all ties with a 12½-inch adzing length, and this would take care of all the present A.R.E.A. standards as to length of tie plates.

The recommendation of the Special Committee on Stresses in Track was that the eccentricity of tie plates should not be over ⅜ in. There is considerable variation in the arrangement and spacing of the spike holes. Where four spikes are used per tie plate, the variations in spacing are from 1½ to 4½ in. A good spacing from the standpoint of the tie would be from 3 to 3½ in. between spike holes.

The following recommendations are made:

"1. In view of the interdependence between rail joint and tie plate design and the fact that as far as the tie is concerned, the standard for pre-boring and adzing can be made to conform to the design requirements for joints and tie plates, your Committee respectfully suggests that this subject be reassigned to the proper committee, with instructions to consider the following suggestions in preparing a standard or standards of tie plates which will result in standardized adzing and boring:

"1. A single standard of cant.

"2. A standard distance between centers of spike holes in all tie plates at the edges of the rail base.

"3. The lengths and eccentricity of tie plates to be standardized.

"4. A standardized location for the grooves cut in the cross-ties, both as to distance between the two grooves under each rail and the distance (gage) between the grooves under one rail and those under the other rail so that all cross-ties may be pre-grooved to a single standard regardless of the rail section to be used, making the necessary accommodations for different rail sections in the designs of the tie plates for different rail sections.

"5. To particularly expedite standards for plates and boring for the new 112-lb. and 131-lb. rail sections."

The President:—The recommendations of this Sub-Committee will be given consideration by the proper committee. The report will be filed as information. Are there any questions you would like to ask the Committee on this subject?

Chairman W. J. Burton:—The next subject, A Method of Predicting Tie Renewals, including a Period of Change from Untreated to Treated Ties. This subject may, on

first reading, appear rather innocent, but I want to assure you that it is something on which we have done a great amount of work. It points out new ideas which I am sure will be new to a great many maintenance men, and points a way to the supervision of tie renewals and related matters, which will be most helpful in promoting ultimate economy. This report has been prepared by Mr. Crugar, who will present it.

Mr. E. L. Crugar (Wabash):—The report of the Sub-Committee will be found beginning on page 798 of Bulletin 363. Your attention is called to a typographical error in the fourth line of the second paragraph on page 799. This refers to Fig. 5 instead of Fig. 6.

The report as it is here presented is the result of tabulations and charts in such volume as to make it impossible to present all of the details. We have endeavored to present the suggested procedure to be followed in the working out of your own problem of predicting tie renewals on whatever average life you may be obtaining from the grades and quality of ties you are using. The so-called 8, 10, 20 or 25-year ties on one road may be something else on another road. In this connection your attention is called to the last paragraph on page 799, Comparisons of Ties Renewed per Mile. When all is said and done, your own tie requirements per mile, or on any other unit that may be designated, is measured by what you are getting from the tie used. Comparisons are very valuable but to be of value they must be reduced to a comparable basis. The report is submitted to you as information. Whether it is of value is left for your determination. We believe the assignment has been completed, but, nevertheless, we will gladly answer any inquiries that members may write us in regard to the subject, and if reason is shown for revision, the subject can be reopened for that purpose.

The President:—The report will be received as information, but I am sure the Committee would like to have some discussion on this very interesting subject.

Chairman W. J. Burton:—I should like to start a little discussion by pointing out some of the high spots in this report. In the first place, I want to urge every maintenance man who has to do with tie programs to go into it far enough to get the idea. It is very difficult to get it unless you actually go through the motions of making these estimates.

One of the important points is that there are practically no roads, I think I could say there are no roads, using creosoted ties who have used them long enough for constant normal renewals, or for what the Committee calls the "normal annual renewals", to have become constant. In other words, the effect of changing from untreated to treated ties creates certain disturbances in the number of ties required this year as compared to last year, or next year as compared to this year, in such a way that that requirement of ties to merely maintain, not to improve nor to drop back, varies each year and varies very considerably.

It is commonly thought that when a road adopts high-class creosoted ties in place of untreated ties, it must wait for a very long period of years before it receives any substantial benefit. Some have thought that it must wait until practically all of the old ties are out of the track before any benefit is received. This report should convince anyone that that idea is very erroneous, and that the benefit begins to be felt after the second, third or fourth year, and that in a very short time renewals drop to even below the level corresponding with the average life of the creosoted ties. For example, if the creosoted ties have an average life of twenty years, corresponding with a 5 per cent renewal, the renewals in a few years not only will drop below 5 per cent but may even drop to zero. This is hard to believe, but it is exactly the way it works out.

Another important point which this report clears up concerns estimates of deferred maintenance. One easy method, and one which has frequently been followed in such estimates, is to obtain a normal renewal by a process of averaging renewals for three or four of what are considered normal years. For instance, we might average the renewals for the years '28, '29 and '30 and call that average our normal, and then perhaps make some adjustment for decrease in traffic, and then say that the difference between what we did renew and this normal represents deferred maintenance. But this method would produce a wholly erroneous result, a much greater figure than the true figure.

I want to call attention to the diagrams on page 800 and also the diagram on the opposite page. There is no theory connected with this compilation that is at all out of harmony with actual fact. If, for instance, we were to build a new railroad out of untreated ties which had a relatively short average life, the number of ties required each year for merely maintaining the track, not improving it or changing it, is represented by the upper curve.

You will notice that when the road is new, there is a considerable fluctuation extending over a period up to about 30 years. Beyond then the curve becomes almost a straight line. Where ties are longer lived, as shown by the lower curves, there is a similar vibration or variation in normal requirements. To be particularly noted are the great magnitude of these vibrations, that is the great variation from one peak to the next hollow, and that in the case of the long-lived ties, the period of years required before the renewals settle down to a constant normal is very great.

The change from the use of short-lived untreated ties to long-lived treated ties is indicated in the diagram on page 801. In this case it will be noted that the normal requirement actually touches the zero line in about twelve or thirteen years. There is nothing about that result which is not absolutely correct, as far as we can determine. Of course disturbances due to financial conditions, variations in traffic, and so on, will create minor irregularities in these curves, but if we stick to the definition that we are merely maintaining, and that we do not improve or do not lessen the degree of maintenance, these results are absolutely correct. I am sure it is a new thought to many that the tie renewal just sufficient to maintain is not constant year by year.

The next subject is reported on page 809, Type of Tie Plate Best Adapted for Use with Pre-adzed Ties. The Chairman of this Sub-Committee is absent and I will read the report as it is not long.

(Chairman Burton read the matter appearing on page 809.)

The President:—This report will be received as information. Is there any discussion? Are there any questions you would like to ask?

Chairman W. J. Burton:—The next subject is found on page 810, "Economy of Use of Tie Plates which are Secured to the Tie Independently of the Rail Fastenings, with Particular Reference to the Effect on Tie Life." This report will be presented by Mr. Bolin, Chairman of the Sub-Committee.

Mr. W. C. Bolin (Baltimore and Ohio Chicago Terminal):—The report of Sub-Committee (10) is to be found in Appendix H, Bulletin 363 on page 810.

There is an error in the twelfth line of the report. The sentence reading, "Spikes used with class (a) are usually cut spikes or lag screws," and so forth, should have the first word changed from "spikes" to "independent fastenings," so that it will read, "Independent fastenings used with class (a) are usually cut spikes or lag screws," and so forth.

On heavy duty track, rail is renewed several times during the life of a treated tie, with resulting abuse to the tie from adzing and spiking. Frequent re-adzing and re-spiking of the tie damages the tie fibers and permits easier introduction of moisture beyond the treated depth, with resulting decay and loss of holding power of the spike.

Some types of rail fastening used with independently fastened tie plates would appear to minimize this abuse.

Failure of the tie at the rail seat results from the mechanical wear and shattering, as well as from the decay and loss of holding power of the spike. Larger and heavier tie plates distribute the traffic load over a greater tie area. Independent fastening of tie plate reduces the amount of motion and friction between the steel plate and the wood tie. These have materially reduced the mechanical wear and shattering of the tie.

To the extent that the larger tie plates spread the mechanical wear over a greater tie area, even though accompanied by the use of more spikes, and to the extent that independent fastenings may make unnecessary re-spike of the ties on account of rail renewal, widening gage or loosening of the spikes, the *abuse* of the tie is reduced and the *use* of the tie is increased—improved tie life may be expected.

The Committee makes no finding as to the economy that may be secured. The report is submitted as information.

The President:—The report will be so received. Is there any discussion on this subject?

Chairman W. J. Burton:—The next subject is Methods of Inspection for Renewal of Ties, Checking Thereof and Adherence Thereto. This, of course, refers to the inspection of the ties in track, not of the material. Mr. Belcher, Chairman of the Subcommittee, will present the report.

Mr. R. S. Belcher (Santa Fe):—This report is on pages 811 to 828. The report this year is a digest of sixty-one replies to a questionnaire which appears on page 351 of Vol. 34 of the Proceedings. Your Committee has endeavored to consolidate the information contained in the replies to the questionnaire into a story of the methods used for the determination of annual tie renewals, including expressions of opinion relative to the use of these methods and possible improvement in them.

Your Committee takes this opportunity to express its appreciation of the hearty response of the Engineers who answered our questionnaire and the complete yet concise manner in which each phase of the subject was covered.

On these sixty-one railroads located in all parts of the country, it is to be expected that the wide range of conditions will call for a considerable variation in the methods used for the determination of annual tie requirements. Possibly no one method suitable for use under all conditions can be established. However, your Committee is of the opinion that the general conclusions given on pages 827 and 828 may be applied under most conditions. This report is offered as information.

The President:—It will be so received. Are there any questions you would like to ask Mr. Belcher?

Chairman W. J. Burton:—This completes the report excepting for the revision of the Manual. The suggested revisions are found on page 780 and the recommendations will be made by Mr. John Foley.

Mr. John Foley (Pennsylvania):—The Committee has been reluctant to make changes in the standard until they seemed almost necessary and highly desirable. The reasons for the proposed changes are enumerated in the report in connection with each recommendation.

Section 16 refers to the split in the tie. The changes simply are that instead of 10 in. being acceptable, the split is reduced to 5 in. and instead of the statement which implied that a single anti-splitting iron would be satisfactory, it is now made clear that effective protection from splitting may require more than one iron.

It is moved that the present form be changed to the proposed form and read:

"16. Split. One which is not more than 5 inches long will be allowed, provided sufficient satisfactory anti-splitting devices have been properly applied."

The President:—While it is not the custom of the convention to discuss definitions on the floor, a brief reference to the definitions or objections to them in their form will be received. However, if there is any particular change in the wording, that may be in the nature of editing, will you please take it up with the Secretary? You have heard the motion. Is there any discussion? All in favor say "aye"; contrary. It is carried.

Mr. John Foley:—The specification under which we have operated for the past dozen years has, under Dimensions, tolerances which seemed necessary at the time it was adopted. As the manufacture of ties has improved in character, those tolerances seem no longer necessary. Therefore paragraph 20 on Dimensions has been reduced to what becomes a very simple rule. Ties may not be any smaller than the standard dimensions called for, but they may in all cases, length, thickness and width, be 1 inch larger. The revised paragraph thus becomes:

"20. Dimensions. The lengths, thicknesses and widths specified are minima for the standard sizes. Ties over 1 inch longer, thicker or wider than the standard sizes ordered will be rejected."

The adoption of that change in the Specification for Cross-Ties is moved.

The President:—It has been moved and seconded that the change in Specification of Cross-Ties under the heading of Dimensions be adopted. Is there any discussion on this? All those in favor will vote "aye"; contrary. It is carried.

Mr. John Foley:—For the same reason a similar change is recommended in the Specification for Switch-Ties, and it is moved that paragraph 20 be changed as follows:

"20. Dimensions. The lengths, thicknesses and widths specified are minima for the standard sizes. Ties over 1 inch longer, thicker or wider than the standard size ordered will be rejected."

The President:—There has been moved and seconded the adoption of this change in Specification for Switch-Ties under Dimensions. Is there any discussion?

Mr. J. C. Irwin (Boston & Albany):—I just want to ask Mr. Foley if any study has been made as to the probable effect on the price of ties. Do you think there would be any effect?

Mr. John Foley:—No effect.

Mr. J. C. Irwin:—Have you satisfied the manufacturers that that will be the case?

Mr. John Foley:—Yes.

The President:—Is there any further discussion? Are you ready for the question? All those in favor will say "aye"; contrary. It is carried and so ordered.

Mr. John Foley:—In the Manual on page 121 there is an illustration of cross-sections of ties which are in harmony with the standard specifications. The changes which you have just adopted require correction of that diagram. At the foot of page 781 you will find what they are. In line 4, column 5, the thickness becomes 8 in. instead of 8 to 9 in., and the bottom width should be 9 to 12 in. instead of 9 to 15 in. In column 6 the thickness should be 8 in. instead of 9 in. In line 5, column 6, the width becomes 10 instead of 12 in. These necessary changes in that diagram are due to the action you have already taken in amending the specifications.

Their adoption is moved.

The President:—Is there any discussion on this? All those in favor will say "aye"; contrary. It is carried.

Chairman W. J. Burton:—That completes the report.

The President:—This Committee has for many years made contributions of great value to the information on cross-ties. Their report this year contains information that will be of advantage to the Track Committee in their design of tie plates. They will now be excused with the thanks of the Association (Applause).

## DISCUSSION ON WOOD PRESERVATION

(For Report, see pp. 713-777)

Mr. F. C. Shepherd (Boston & Maine):—The report of Committee XVII—Wood Preservation, is found on page 713 of Bulletin 363.

The first report, Revision of Manual, is shown under Appendix A on page 714. This report will be rendered by Mr. Steinmayer, Chairman of the Sub-Committee.

Mr. O. C. Steinmayer (Canada Creosoting Company):—With a view to harmonizing the specifications of the various associations relating to the same product, the Committee has been collaborating with representatives of the American Wood Preservers' Association and the American Society for Testing Materials on creosote and creosote-coal tar solutions.

Pursuant to this, your Committee recommends the revision of present standards involving more particularly the withdrawal of clause 5 relating to the specific gravity of fractions and the addition of some footnotes which will aid in arriving at the authenticity of the product.

The character of tar has changed because of the increased proportion originating from coke ovens of modern design and method of operation, with the result that creosote distilled therefrom very often has gravities of the fraction 235 to 315, also the fraction 315 to 355, lower than those now embodied in clause 5. A lowering of the gravity requirements for these two fractions to the limit as embodied in the footnote therefore seems most advisable.

In these footnotes attention also is called to the presence of solids in the fraction between 210 and 235 deg. C. when cooled to 25 deg.; also the increase in quantity of insoluble matter in benzol, in creosote, due to changes in its characteristics after repeated use in treatment. Mention is made of the presence of tar acids in varying amounts in all fractions up to 315 deg. C. This reference to tar acids makes it necessary to adopt a standard method for their determination in creosote. All these remarks apply equally to creosote-coal tar solution as well as to creosote itself.

Grades 2 and 3 creosote under present conditions of the tar distilling industry are items of special manufacture. There appears to be no good reason why specifications for non-existing grades should be continued.

Your Committee therefore recommends a revision of the specification for creosote, grade 1, also a revision of the specifications for creosote-coal tar solution now appearing in the Manual, and the withdrawal of specifications for creosote, grade 2 and creosote, grade 3.

I move the revision of the present specifications for creosote, grade 1, to conform to the recommendation as shown at the bottom of page 715 and page 716 for publication in the Manual.

The President:—You have heard the motion, gentlemen, on the adoption of the revision of specification for creosote, grade 1. Is there any discussion on this subject? All those in favor will say "aye"; contrary. It is carried.

Mr. O. C. Steinmayer:—I move the withdrawal of specification for creosote, grade 2, and creosote, grade 3, now appearing on page 1287 of the 1929 Manual.

The President:—You have heard the motion. Is there any discussion on the withdrawal of the specifications? Has anyone any objection to their withdrawal? If not, all those in favor say "aye"; contrary. It is carried.

Mr. O. C. Steinmayer:—I move the revision of present specifications for creosote-coal tar solution to conform to the recommendations as shown in the lower part of page 716 and 717 for publication in the Manual.

The President:—You have heard the motion. Is there any discussion on this specification? All those in favor will say "aye"; contrary. It is carried.

Mr. O. C. Steinmayer:—I move the adoption of Standard Methods for the Determination of Tar Acids in Creosote as shown at the bottom of page 717 and continued to page 719, for publication in the Manual.

The President:—Is there any discussion on these standard methods for the determination of tar acids in creosote? All those in favor will say "aye"; contrary. It is carried.

Chairman F. C. Shepherd:—The second report of this Committee, Service Test Records for Treated Ties, is shown under Appendix B on page 719. In this report the Subcommittee shows its table on tie renewals per mile maintained on various railroads, up to and including 1932, and submits reports of special test tracks on some five different railroads. This report is offered as information.

The President:—It will be so received. Is there any question you would like to ask in connection with it?

Chairman F. C. Shepherd:—Subject (3) Piling Used for Marine Construction is shown on page 729 under Appendix C. This report will be described by Mr. Atwood, Chairman of the Sub-Committee.

Mr. Wm. G. Atwood (Consulting Engineer):—This report is really a research report carried on from the work of the National Research Council and amplified by work which we have been able to initiate in the ten years since that organization was disbanded. We have received a very high degree of cooperation from the various governmental agencies, the Chemical Warfare Service of the Army and the Bureau of Yards and Docks of the Navy. So far as caring for the test specimens and making reports on them, it has really been very surprising the accuracy and care with which this work has been done. Further, the Chemical Warfare Service have, until the recent reduction in expenditures, been able to carry on a considerable amount of original research, looking for more economical and more efficient preservatives. Like all research, the results are still in question, but it is an extremely valuable thing to have this work being done as it has been done by the government agencies. There is no particular point to which to call attention in the report, except perhaps the success of the tests of some tropical timbers of Panama. The Governor of the Canal Zone has consistently been very interested in this subject, regardless of whom he might be. They are developing some information, particularly along the East Coast, which may ultimately be of great value to those responsible for the maintenance of marine structures.

Outside of the report there is one caution that I should like to bring to the attention of maintenance officers, and that is the extreme variability in the attack of marine borers. They go in waves. Places where there has been freedom from an attack, or that has had a light attack may at any time have an intensified attack.

I was talking with a marine biologist who did a large part of our work on the National Research Council Committee, only a few days ago, and he called my attention to a very heavy increase in the last two years in the attack of borers along the New England Coast. There have been many points in Massachusetts Bay where there never have been any borers, Plymouth being one, and several structures in that vicinity have been destroyed within the last two or three years. He said it was also true that borers had been found in the inner harbor of Boston where they have never been known before, and the attack in Portland was heavier. Therefore, the maintenance officers on

marine structures should keep very close watch of their structures, even though they have had no previous history of attack. How far that goes in connection with New York Harbor is a question. Just before I left home I heard a rumor of a heavy borer attack pretty well up the Hudson. Whether that is true or not I was not able to find out before I left. The report is offered as information.

The President:—It will be so received. This is very valuable information. If there are any questions you would like to ask the Committee, please do so.

Chairman F. C. Shepherd:—Report (4), Specifications for Treatment of Air-Seasoned Douglas Fir, is found listed under Appendix D on page 750. This report will be rendered by Mr. Belcher, Chairman of the Sub-Committee.

Mr. R. S. Belcher (Santa Fe):—The work of your Committee on this subject which began in 1928 may be divided into three parts: First, a study of the treatment of Douglas fir piling timbers which have given long service, the methods which were used for the treatment of this fir, and the penetration of preservative accomplished by these treatments.

Second, a study of the practice of incising or perforating Douglas fir ties and timbers, the improvement in penetration and absorption of preservative obtained thereby, and the effect of incising upon the strength of the timber; third, a study of the effect on quality of treatment of the various manipulations of the treating cycle, using experimental equipment but along the general lines of the treating methods now in general use.

The report of the study of the Douglas fir piling and timbers which have given long service appears in Vol. 30 of the Proceedings. The report of the study of incising and treatment manipulations appears in Vol. 34 of the Proceedings. This report also included the proposed specifications which were presented last year as information, with the recommendation that they be referred to other interested committees for consideration and criticism. These committees have approved the specifications, and your Committee is now presenting the specifications for inclusion in the Manual.

I should like to make a correction on page 752, in view of the change in standard preservatives just approved. Under the heading "Preservative" and opposite the word "Creosote" delete "classes one, two and three." In other words, it will read:

The preservative used shall conform to one of the following standards of this Association: Creosote, Creosote-Coal Tar Solution, Zinc Chloride.

I move the adoption of the Specifications for the Treatment of Air Seasoned Douglas Fir for publication in the Manual.

The President:—It has been moved and seconded that we adopt the Specifications for the Treatment of Air Seasoned Douglas Fir as shown on pages 750 to 754, inclusive. The motion is before you for discussion, but in order to amend or discuss these different items, I will ask the Chairman to read each one by its caption, and if there is any discussion please rise immediately and you will be recognized.

(Mr. R. S. Belcher read the headings of the specifications, beginning on page 750.)

The President:—Is there any discussion on this subject? Are you ready for the question? All those in favor will vote "aye"; contrary. It is carried and so ordered.

Chairman F. C. Shepherd:—The fifth report, Destruction by Termites and Possible Ways of Prevention, is shown under Appendix E on page 755.

We call attention to the fact that on page 713 there is a printer's error where it indicates Appendix D instead of Appendix E. This report will be rendered by Dr. von Schrenk, Chairman of the Sub-Committee.

Dr. Hermann von Schrenk (Consulting Timber Engineer):—This report is again in the nature of a progress report of research work dealing with insect destruction of timber structures. On the first page, page 755, we have given an account of the very

interesting set of experiments initiated last year by the R.C.A. Communications on Long Island.

The termites for some reason or other have been particularly active in the vicinity of New York this last year, and through the cooperation of Dr. Snyder of the U.S. Bureau of Entomology, a very large number of poles have been installed by the R.C.A. Communications to try out the effect of different soil poisons.

The second part of our report deals with the international exposure test under the auspices of the Federal officials. I call attention on page 759 to the fact that Fig. 2 was reversed, so that if you want to see what it should be you have to turn it upside down.

One of the important points which we call attention to this year is indicated at the bottom of page 759 and 760. It refers to the final report of the California Termite Investigations Committee. I am very sorry that the very large volume was not received in time so that we could have given a review commensurate with the significance of this report in our this year's Proceedings. We wish, however, to call attention to the fact that anybody interested in the activities of these insects—I may say again, as we did last year, they seem to be increasing—by all means should order this volume. It costs \$5 and can be purchased as indicated on page 760 from the University of California Press, Berkeley, Cal.

The last part of our report deals with some additional notes on the wharf borer. Col. Atwood said that the marine borer is appearing in places where they have been free from it. The wharf borer, instead of attacking the marine structures from the water, is attacking marine structures from the air. If both the marine and the wharf borers keep on going you can see what is liable to happen to the untreated wharf structures. Very little is known of this insect as yet except as indicated in our last year's report, that it has been found on the Atlantic, Gulf, and the Pacific Coasts.

We are particularly anxious to have the members of the A.R.E.A. watch for its appearance, because if they carry out the same method of appearance that the marine borers and the termites have, we may be in for a rather serious attack almost any time. At any rate, it seems worth while to describe the insects and to suggest that a very careful watch be kept of their appearance, with the further request that the Committee be notified so that we may give it more detailed attention.

As stated, this report is submitted as information.

The President:—It will be so received. Are there any questions you would like to ask Dr. von Schrank?

Chairman F. C. Shepherd:—The sixth report, Loss of Preservative in Treated Ties in Track Due to Use of Oil-Burning Weed Destroyers, is found on page 762 under Appendix F. This report is a continuation of investigations and studies with reference to loss of preservative in treated ties due to repeated use of oil-burning weed destroyers. Reports have already been presented in 1930 and 1932, and the Committee now submits a final report with the recommendation that it be accepted as information and the subject be discontinued.

The President:—The report will be so received and the question of discontinuance will be submitted to the Outline of Work Committee for action.

Mr. R. C. Bardwell (Chesapeake & Ohio):—In the President's Message to Committees, dated April 17, 1933, Subject (6) of Committee XVII—Wood Preservation, reads: "Loss of preservative in treated ties in track due to repeated use of oil-burning weed destroyers and effect of blowing off locomotives on line of road, collaborating with Committee XIII—Water Service, Committee XXII—Economics of Railway Labor and Committee XXVII—Maintenance of Way Work Equipment."

The report presented by this Committee in Appendix F appears to take care of the assignment regarding oil-burning weed destroyers but entirely neglects that part of the assignment concerning the effect of blowdowns of locomotives. We consider the effect of blowdowns of locomotives on treated ties to be an important subject. I know there has been considerable study made of this. I personally collaborated with Dr. von Schrenk. I do not think this subject should be discontinued, but it should be reassigned to the Committee and a report made in accordance with the assignment last year.

Chairman F. C. Shepherd:—We considered that those two assignments were separate subjects. We have not discontinued any action on the second subject but have done work on it. We did not feel that we had gone far enough to present a report on it. It is in our studies for the next year's report and will be continued. We thought that we would clean up this part of it because we had gone as far as we could go, and recommended that this information be accepted and the matter dropped in so far as the oil-burning machines were concerned.

The President:—The Chair asks that the Chairman of the Committee on Outline of Work take note of these remarks and take proper action.

Chairman F. C. Shepherd:—Methods of Protection of Treated Materials in the Field. This report is found on page 765, Appendix G.

Last year this Sub-Committee presented a tentative report for suggestions, criticism, additions, and now presents this year a final report with the recommendation that it be received as information and the subject be continued, with the recommendation to the Committee on Outline of Work that collaboration of Committee III—Ties, Committee VII—Wooden Bridges and Trestles, Committee XVII—Wood Preservation, be directed with Committee XII—Rules and Organization, to the end that approved rules be published in the Manual under the jurisdiction of Committee XII.

The President:—The report will be received as information, and the recommendation of the Committee will be given consideration by the Outline of Work Committee.

Chairman F. C. Shepherd:—Report (8), Service Test Records of Structural Timber Including Piling, will be found on page 770 under Appendix H.

In developing this subject, the Committee, through circular letters to various roads, obtained lists of a large number of bridges and trestles, and data related to the service life of same. As a result, the Committee now publishes four reports:

- (1) Treated bridges that have given outstanding service.
- (2) Treated bridges that have failed or have shown serious defects.
- (3) Untreated bridges that have given outstanding service.
- (4) Untreated bridges that have failed or shown serious defects.

On page 774 there is a correction. The word "Conclusions" should be dropped to below the next paragraph, so that the Conclusions will read as follows:

"Generally it is evident that creosoted timber trestles give prospect of life two or more times that secured from untreated timbers, unless the latter is of timber by nature resistive to decay, or it is in structures where service requirements and climatic effects are moderate or light.

"In creosoted timber structures that have shown early failures, the record shows them to have been caused by inadequate protection of surfaces exposed by field cutoffs, borings and destructive handling. Such defects limit the life of creosoted timber irrespective of its kind, whether pine, fir, cedar, oak or other timber of structural grade susceptible of treatment.

"Structures of untreated timber are generally not considered to be economic except where light service conditions, nearby supply and low costs prevail."

Your Committee now recommends that these conclusions be accepted for publication in the Manual, and that the remainder of the report be accepted as information and the subject be discontinued. I so move.

The President:—It has been moved and seconded to adopt and include in the Manual the three paragraphs under Conclusions on page 774. Is there any discussion? All those in favor will say "aye"; contrary. It is carried. The balance of the report will be received as information.

Chairman F. C. Shepherd:—That completes our report.

The President:—This Committee is to be congratulated on its fine work. We will now excuse them with the thanks of the Association (Applause).

## DISCUSSION ON WATER SERVICE AND SANITATION

(For Report, see pp. 621-643)

Mr. R. C. Bardwell (Chesapeake & Ohio):—The report of Committee XIII—Water Service and Sanitation, is presented in Bulletin 362, pages 621 to 643, inclusive.

Before submitting this report, it is believed that it would be fitting for the Committee to announce that it sustained a severe loss during the past year through the death of one of its distinguished members, Dr. James H. Gibboney, Chief Chemist of the Norfolk & Western Railway. Dr. Gibboney was also Chairman of the Arrangements Committee at the time of his death. A memoir to Dr. Gibboney is presented on page 622.

Consideration has been given during the year to possible revision of the subject-matter in the Manual pertaining to Water Service and Sanitation, but the present set-up seems to be in very good shape. There are only a few suggested changes in view which are being studied, and recommendations will be presented next year.

The study on assignment (2), cause and extent of pitting and corrosion of locomotive boiler tubes and sheets, has been continued, and a progress report is given in Appendix A, to be presented by the Sub-Committee Chairman, Mr. J. H. Davidson.

Mr. J. H. Davidson (Missouri-Kansas-Texas):—The report on the cause and extent of pitting and corrosion of locomotive boiler tubes and sheets appears on pages 623 and 624 of Bulletin 362. The report is a brief review of progress made since the subject was assigned for study.

The outstanding method for inhibiting pitting and corrosion in locomotive boilers is to maintain the proper caustic alkalinity in the boiler water. References to previous reports are given for those who desire to study this subject in more detail.

The fact that boilers of stored locomotives may sustain serious damage by pitting and corrosion during storage periods makes it advisable for those responsible for providing suitable locomotive boiler feed water, to see that all concerned are informed regarding the possibility of such damage, to the end that it will be guarded against, and the quality of the feed water will not be unjustly held responsible for such damage. This report is offered as information.

The President:—It will be received as such. Are there any questions you wish to ask the Committee?

Chairman R. C. Bardwell:—The report on assignment (3), methods and value of water treatment with respect to estimating and summarizing possible savings effected, is given in Appendix B, and will be presented by the Sub-Committee Chairman, Mr. R. E. Coughlan.

Mr. R. E. Coughlan (Northwestern):—During the past year your Committee has endeavored to further summarize the monetary value of the various methods of water treatment.

It has been a physical impossibility to obtain definite records of any value from all of the larger railroads comparing the savings before and after definite water treatment programs have been instituted, because of the fact that prior to the installation of water treatment, many of the roads have no definite record of the damage done by unsuitable water over any length of time. We have found, however, that all of the roads which have a definite program installed are now showing a decided reduction in shop repair and material formerly purchased to replace that destroyed by unsuitable water.

This, together with the increased mileage between boiler washings, and the numerous government extensions on boiler flues over the four-year limit, which all of the larger railroads are now obtaining, clearly indicates that the monetary value is becoming a decided factor in reducing operating expenses. The report this year is offered as information.

The President:—It will be received as such. Are there any questions?

Chairman R. C. Bardwell:—The final report on assignment (4), developments in pipe joints, is presented in Appendix C. This subject has been given a very considerable amount of study under the very able direction of Mr. R. L. Holmes, and it is believed that the information shown is an important contribution of special interest to Engineers. The report will be presented by the Sub-Committee Chairman, Mr. R. L. Holmes.

Mr. R. L. Holmes (Texas & Pacific):—Sub-Committee report No. 4, developments in pipe joints, is found on page 625, Appendix C, of Bulletin 362.

The salient points of the report are the number of joints available, many of which have been thoroughly tested.

No doubt much difficulty was experienced with the screw joints prior to the adoption of the American standard, and a similar condition will exist in fire fighting equipment until the National Underwriters' Standard couplings are adopted.

Many of the mechanical joints for cast iron pipe have been tested and proven satisfactory.

Practically no changes have been made in the bell and spigot cast iron pipe joint since its first use.

Special mention of the use of cement as a joint filler will be found on pages 630 and 635 of this report and complete specifications covering the use of cement as a joint filler may be had by communicating with your Sub-Committee Chairman.

I move this report be accepted as information.

The President:—This report will be so received. Is there any discussion on it?

Chairman R. C. Bardwell:—The subject of mosquito control is of considerable importance to railroads operating through the southern section of the country. Mr. Van Hovenberg, Sanitary Engineer for the St. Louis and Southwestern Railroad, has prepared a report on this subject under assignment (5). In the absence of Mr. Van Hovenberg, the report will be presented by Mr. H. F. King.

Mr. H. F. King (Erie):—The paper on "Essentials of Mosquito Control" will be found on page 637 of Bulletin 362. It describes briefly the range of recent engineering work aimed at affording relief to human beings at work as well as at play, through control of pest mosquitoes and refers to the economics of these projects.

In connection with disease carrying mosquitoes, the paper refers to studies being made in connection with the long distance transporting of new varieties of mosquitoes over our borders by airplanes and to the protection of our borders from the admission of infected mosquitoes or of infected human beings, and to the methods in vogue for the protection of our own people. The effect of impounding water for power or other

purposes in connection with the introduction of disease carrying mosquitoes, and the steps taken by our several states to combat this is described. The effect of malaria on railroad operation is referred to with a summation of the interest taken by southern railroads in applying relief methods. This paper is offered as information.

The President:—This report will be received as such. Are there any questions?

Chairman R. C. Bardwell:—The Committee is still studying assignment (6) design and maintenance of track pans for locomotive water supply, and again we announce that we hope to have the final report next year.

The study on assignment (7), methods for analysis of chemicals used in water treatment, has been held up a little, awaiting report and conclusions of work by a similar committee of the American Waterworks Association on which your Committee is represented. We hope to have a further report on this subject next year.

Due to the unsettled conditions in the political field for the past year, there have been no new developments to report from either Federal or State authorities on regulations pertaining to railway sanitation. It is therefore recommended that that subject be continued.

Assignment (9), disinfectants, fumigants, and cleaning materials, is of importance to railroads, as a considerable expenditure is made annually for such materials, and the information available for protection of the purchaser is limited. The progress report on this assignment will be presented by the Sub-Committee Chairman, Mr. W. P. Hale.

Mr. W. P. Hale (Rock Island):—The report of the subject assigned to the Committee may be found on page 640 of Vol. 35.

The subject assigned to the Committee has been deemed of sufficient importance to warrant extended investigations, since the assignment covers a scope of varied materials of innumerable usages, and represents a considerable expenditure on the part of the various railways. For these reasons, the report for this year will consist of a general outline of the scope of the subject, a differentiation of the terms "disinfection", "fumigation" and "deodorization" and a digest of the more common compounds for the purpose required.

Some idea of the scope of the assigned subject may be obtained from the following outline of correlated purposes for which disinfectants, fumigants, deodorants, and cleaning materials are used on railways, and on which detailed report will be prepared before conclusion of the assignment:

1. Disinfection and/or deodorization of passenger cars, cattle cars, cattle pens, poultry cars, cotton cars, copra and bone cars.
2. Fumigation of grain cars, grain elevators, camp cars, passenger equipment, hotels, eating houses, grain houses, etc.
3. Car cleaning, cuspidor cleaning, washing floors and woodwork and windows, drinking water disinfection, sterilizing water tubs, cisterns or tanks.
4. Cleaning and deodorizing cars or buildings used in handling fish, milk and cream, dressed and live poultry, etc.

All these matters are pertinent to the assigned subject "Disinfectants, Fumigants, and Cleaning Materials," and will be discussed in future reports.

Considerable confusion exists between disinfectants and deodorants.

"Disinfection" means the destruction of the agents causing infection. An object is said to be "infected" when it is contaminated with disease-producing bacteria. It is "disinfected" by destroying these bacteria.

A deodorant is a substance which has the power to destroy or neutralize unpleasant odors, such as those arising from organic matter undergoing fermentation or putrefaction. Such substances must be carefully distinguished from disinfectants. Deodorants are not, necessarily, disinfectants and disinfectants do not necessarily have an odor

No confidence can be placed on disinfectants simply because they smell of chlorine or carboic acid, or possess the color of permanganate. Deodorants destroy smells; disinfectants destroy germs. Many of the disinfecting agents are also deodorants, but all deodorizing substances are by no means disinfectants.

Fumigation consists of liberating fumes or gases with the object of destroying germs or vermin, insects, rats, mice, and other small animals, acting as carriers of infection, or destroyers of food products or other matter. Fumigation cannot take the place of disinfection. It is chiefly useful in preventing the spread of insect-borne diseases, and the destruction of damage to food and other products by rodents or insects.

In many instances certain types of fumigation are required by Federal statute. One instance is the required fumigation of cotton freight cars infected with Mexican pink bollworm, a very serious pest to cotton.

The first car fumigation houses for this purpose were built during 1919. At the present time there are six such houses along the Mexican border, with capacities ranging from 20 cars down. For several years liquid hydrocyanic acid has been used as a fumigant and satisfactory results have been obtained.

Another instance is the regulations promulgated by the Secretary of Agriculture, at present embodied in B.A.I. Order 309, under which the Bureau of Animal Industry is charged with the disinfection of premises and vehicles which may have become infected by diseased animals in the course of interstate transportation. This order specifically states as to when, where, and how cleaning and disinfecting of such cars, boats, yards and premises shall be done and lists the disinfectant.

Any complete report on the subject assigned must of necessity, to be of any value to the members of the Association, contain definite instructions concerning the use of the various materials, describe the particular compounds suitable for each particular purpose, and detail methods for their successful and economic use. This phase of the subject will be taken up in later reports.

Sub-Committee (9) asks that the material submitted be accepted as information and that the subject be continued another year.

The President:—It will be so received. Is there any question you would like to ask the Committee?

Mr. W. A. Radspinner (Chesapeake & Ohio):—The Southeastern Underwriters representative said there had come to his attention the fact that hydrocyanic acid gas resulted in poisoning in some cases. They took it up with the medical profession, and there was disagreement as to what the effect would be. Some of them contended that a man exposed to this gas, and who then did not go near it again for sometime, would not be affected. The other group claimed that if he was exposed to it he would retain the cyanid, and as soon as he accumulated enough of it it would kill him.

Mr. W. P. Hale:—My understanding of the use of the hydrocyanic gas is that if a person is affected by—or food products or other article are contaminated with—this gas during process of fumigation, the simple method of an hour's exposure in the outside air will eliminate any danger. Bedding which has been exposed for a period of seven or eight hours to the hydrocyanic gas can safely be slept on within an hour after fumigation in the open air.

Chairman R. C. Bardwell:—That concludes the report.

The President:—This Committee which is composed of experts in their particular line have again submitted some very valuable information. They will now be excused with the thanks of the Association (Applause).

## DISCUSSION ON SIGNALS AND INTERLOCKING

(For Report, see pp. 333-341)

(Vice-President John E. Armstrong in the Chair.)

Mr. P. M. Gault (Missouri Pacific):—The report of Committee X is found on page 333 of Bulletin 360. The first subject the Committee has to report on is the developments of automatic train control. In the absence of the Sub-Committee Chairman, I will present the report. This report is presented as information.

I would call your attention to the roads listed at the top of page 334. The first list of roads have petitioned to discontinue the operation of automatic train control. The last two in the list, Alton, and Southern Pacific, are shown as "pending." The report was written last October. Since that time the Alton petition has been denied, and the Southern Pacific petition has been granted.

In the next list of roads that petitioned to discontinue operation of automatic train control and operate by cab signals in conjunction with wayside signals, the Boston and Maine petition is shown as "pending." That petition has been granted with the understanding that they will operate with cab indicators rather than cab signals, the cab indicators being used to indicate the position of the wayside signals.

I see Mr. Mills of the Bureau of Safety in the room, and if I have misstated either of these conditions I hope you will correct me. Am I right, Mr. Mills?

Mr. S. N. Mills (Bureau of Safety, Interstate Commerce Commission):—The cab indicator on the Boston and Maine calls attention to the fact of whether the wayside indication is clear or restrictive. The engineman is normally governed by the wayside indications. If the cab indication changes from clear to restrictive between wayside signal locations, he is required to stop and is then governed by the low speed restriction.

If the cab indication changes from restrictive to clear between wayside signal locations the engineman is permitted to resume authorized speed after proceeding a train length from the point where the change of indication occurred.

Chairman P. M. Gault:—Thank you, Mr. Mills.

This report refers to Exhibit A and Exhibit B. Exhibit A is found on page 339 and is the proposed standard aspects and indications for continuous automatic cab signals. These aspects and indications have been prepared by the Committee on Automatic Train Control of the A.R.A. and are being submitted to the various Divisions and Sections of the A.R.A. that are interested in this subject. For your information, they were approved by the Signal Section yesterday.

On page 340 is shown Exhibit B, which has the heading "Interstate Commerce Commission, Specifications and Requirements for Continuous Automatic Cab-Signal System." These are the specifications that were issued by the Interstate Commerce Commission to the roads to which they apply. They are shown here as information. They have not been formally approved by the Committee on Automatic Train Control of the A.R.A.

Unless there are some questions, that concludes the report on automatic train control.

Vice-President John E. Armstrong:—The report will be accepted as information.

Chairman P. M. Gault:—Mr. Post will handle the report on Appendix B.

Mr. W. M. Post (Pennsylvania):—This assignment is found on page 335. This Committee has presented several reports showing the savings and increased efficiency

secured in railway operation by signal indications in lieu of train orders and timetable superiorities. This is a final report on this assignment. The assignment for next year has been considerably broadened and will be, as I understand it, developments in railway signaling, which would include this assignment, but is broader.

The Committee presented reports in 1932 and 1933 on the economic results of centralized traffic control installations. In addition to definite money savings due to block and interlocking stations discontinued, and gross ton miles per train hour increased, there is an increase in the margin of safe operation, which results in intangible savings which cannot be definitely determined, but which are nevertheless real.

This report relates to intangible benefits and savings difficult to determine accurately, provided by a centralized traffic control installation.

You will note that the assignment at the head of this report reads as follows: "Increased efficiency secured in operation by signal indication, including remote control of switches, and centralized traffic control, in lieu of train orders and timetable superiorities." There has been considerable confusion as to just what "centralized traffic control system" is and what "remote control of switches" is, and what is the difference between them. At the meeting of the Signal Section yesterday definitions were approved, which I should like to read into the records of this Association.

"Centralized Traffic Control.—A term applied to a system of railway operation by means of which the movement of trains over routes and through blocks on a designated section of track or tracks is directed by signals controlled from a designated point, without requiring the use of train orders and without the superiority of trains.

"Remote Control.—A term applied to a system of operating outlying signal appliances from a designated point to facilitate the operation of trains over a designated section of track or tracks by means of signal indications, timetable and train orders."

You will note that the determining feature of centralized traffic control is that the signals give the authority for the train to move, and practically eliminates the need for the issuance of train orders.

You will note that under the heading "A Centralized Traffic Control System," we state regarding this system:

"1. Reduces number of written train orders.

"2. Reduces errors in the transmission of orders. Orders are transmitted by signals, which are surrounded by mechanical and electrical safeguards. If the control operator displays a signal not intended, protection against conflicting movements is automatically provided.

"3. Eliminates possibility of errors in interpretation or execution of written orders.

"4. Eliminates delays due to waiting for written train orders.

"6. Provides means so that disregard of stop signal indication can be instantly detected by the control operator. The knowledge that the control operator can, by observing the lights on the machine, detect any disregard of a stop signal tends to keep the engineman alert and thus reduces the chance that signals will be passed when displaying stop.

"8. Provides facilities for non-stop meets at passing sidings."

A report somewhat similar to this was presented by Committee I to the Signal Section yesterday, and in the discussion it was stated that a record kept of a certain centralized traffic control installation showed that 50 per cent of the meets were non-stop meets. This is no doubt due to the fact that after the enginemen have had experience running under the centralized traffic control system, they are likely to jockey their trains so that they will have a non-stop meet, that is, they will approach the siding slowly, possibly, so as to time it right, and run slowly through the siding, but it results in a large percentage of the meets being non-stop meets.

In No. 12 you will note we stated that it provides immediate information as to whether or not trains are losing time, and control operator is better able to plan the meets at passing sidings.

This is possible because in a centralized traffic control installation, the control operator has before him a number of light indicators which show him whether or not track sections are occupied.

No. 15 provides facilities for handling peak traffic conditions with no loss of efficiency.

No. 16 provides greater protection for the movement of motor cars and other equipment of the Maintenance of Way department, and control operator can protect their movements by signals when conditions require.

There are no doubt several other intangible benefits and increased efficiency supplied by a centralized traffic control installation. When a similar report was presented yesterday at the Signal Section meeting, in the discussion one of the members stated that a control operator noticed one night that there was something wrong with a certain track section, and he called the maintainer. The maintainer found a broken rail and called the section gang, and they repaired the broken rail without any delay to trains whatever. In another case a track circuit between the ends of a passing siding indicated there was something wrong, and trains were run around the trouble, through the siding, while repairs were being made to a broken rail.

That concludes this report, and it is presented as information.

Vice-President John E. Armstrong:—The report will be so received.

Chairman P. M. Gault:—Supplementing what Mr. Post said, I want to emphasize the fact that there is a difference between centralized traffic control and remote control. Centralized traffic control is a method of train operation, and remote control is a method of switch and signal operation. There is a good deal of confusion in regard to these subjects, especially when it comes to making up reports and classifications.

The next subject that the Committee has to report on is Synopsis of the Principal Current Activities of the Signal Section, A.R.A., Supplemented with List and References by Number of Adopted Specifications, Designs and Principles of Signaling Practice.

Mr. Stradling, who is the Chairman of this Sub-Committee, has been very ill and is unable to be present. I will present the report, which is found beginning on page 336. The first listed is Current Activities of the Signal Section, A.R.A.

Specifications revised.

Drawings revised.

Requisites revised.

New specifications.

New drawings.

Drawings to be removed from the Manual.

Specifications to be removed from Manual.

Requisites to be removed from Manual.

Recommendations to be removed from Manual.

Forms to be removed from Manual.

It is not necessary to read the details of all of these. They are offered as information.

Vice-President John E. Armstrong:—They will be so accepted.

Chairman P. M. Gault:—That concludes the report of the Committee.

Vice-President John E. Armstrong:—The Committee is excused with our thanks for their very excellent report (Applause).

## DISCUSSION ON ELECTRICITY

(For Report, see pp. 343-345)

(Vice-President John E. Armstrong in the Chair.)

Mr. W. M. Vandersluis (Illinois Central):—The report of Committee XVIII—Electricity will be found on pages 343 to 345 inclusive of Bulletin 360. This is a synopsis of the current activities of the Electrical Section.

Your attention is called to the complete report as given in Bulletin 359, Vol. 35 of September, 1933. With reference to assignment (1), the Committee has no new adopted specifications, designs, principles and practices to submit. The summary as given in Bulletin 360 and the complete report as given in Bulletin 359 are presented as information. There are certain Sub-Committee reports which we believe are of particular interest to the members.

Sub-Committee (3), Power Supply. The immediate importance of the development of pre-cooling and air-conditioning of rolling stock, which requires servicing equipment along the right-of-way, is brought to your attention. The questionnaire stresses the importance of standardized voltage and brings out the fact that the majority of systems so far have installed 220 volt, three phase, 60 cycle supply for right-of-way servicing equipment.

The size of the receptacles and plugs required for air-conditioning are much larger than those required for pre-cooling. Standardization of types of plugs and receptacles for use in servicing equipment of the different railroads, in joint stations, is of the greatest importance and should be brought about as promptly as possible.

Under Sub-Committee (5), cooperation in miscellaneous regulations, we wish to call your attention to the negotiations with the Edison Electric Institute covering principles and practices for power wire crossings over railroads, which have been agreed upon. Tentative minimum specifications to accompany the principles and practices have been completed as to the preliminary draft and have been sent to the various members interested for comments.

Upon completion and approval of these specifications by both organizations, your Committee proposes to put up a revised specification covering power wire crossings over railroads to supersede the present specifications adopted in 1921 and now in the Manual.

The report of Sub-Committee (8), Electric Heating, will be presented by Mr. J. M. Trissal, Chairman.

Mr. J. M. Trissal (Illinois Central):—The report on electric heating covers the application of electricity to snow melters, water heaters and space heating, miscellaneous heating equipment, and welding.

In preparing the subject-matter, the Committee collaborated with Committee XXVII—Maintenance of Way Work Equipment on snow melters and electric welding equipment. The information given on electric snow melters covers all of the various types of installations in this country, about which information is available.

Table 1 gives information as to the number of heater units installed, switches equipped and wattage per switch, as well as number of hours of operation during the winter of 1932-33. Various weather conditions encountered and the efficiency of the various types of heaters cause a considerable difference in the installed capacity of the various installations. Detail wiring diagrams showing the methods of controlling snow melters from interlocking towers or other centralized points are included.

The use of electricity for heating water for bathing purposes in various railroad facilities is increasing rapidly, and the various methods which may be employed are discussed. A table is included which shows the capacity of heaters required to heat various amounts of water in a prescribed time.

A detailed description is given of a hot water space heating system installed by the Reading Company.

The use of electricity for babbitt welding pots, sand drying facilities, glue pots, baking ovens and crankcases of automobiles and motor cars, is discussed in a general way.

A glossary of terms used in electric welding as well as desirable characteristics for electric welding equipment are covered in detail, with no attempt being made to compare desirable characteristics with the characteristics available in commercial machines.

The report is submitted as information.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman W. M. Vandersluis:—The work of Sub-Committee (9), application of motors, is, we believe, of particular interest. For the first time there is presented for your information a general classification of motors, their essential characteristics and their proper application for railroad use. This report should be of particular importance to railroad Engineers in order to check the proper application of existing motors and in the laying out of new work.

Sub-Committee (10), clearances for third-rail and overhead working conductors, has submitted a report which brings up to date the data regarding third rail clearances and overhead clearances on existing steam road electrifications.

Sub-Committee (16), application of corrosion-resisting materials to railroad electrical construction, will be submitted by the Chairman of the Sub-Committee, Mr. R. P. Winton.

Mr. R. P. Winton (Norfolk & Western):—We have completed the tests of samples in Cedar Hill enginehouse at New Haven. These tests consist of installing a great number of various materials in the smokejack in order to make an accelerated test of corrosion under extreme smoke conditions.

The chemical and physical properties of these samples are shown on page 108 in Bulletin 359. The loss of weight of these samples is shown in Table 2 on page 112 in Bulletin 359.

In general, the bronzes have given a very satisfactory performance. Some of the aluminum and phosphorus bronzes show considerable pitting and apparent loss of homogeneity near the surface. The aluminum samples, as will be noted from the photographs and tables, were not so satisfactory. In the ferrous group, carbon steels, commercial steel and ingot iron show relatively higher losses. The copper-bearing steels show slightly less loss, and malleable iron still less loss. Some of the chromium and chrome nickel steels show a loss of weight as low as some of the bronzes, but some of them show considerable local pitting.

The copper-nickel steel showed the lowest loss of any of the samples tested, but definite conclusions should be deferred until further tests of this alloy. For your information, this alloy referred to is a steel casting with the addition of Monel, which is a natural alloy of copper and nickel. Apparently this material shows great promise.

We are also carrying on service tests at Hemphill tunnel on the Norfolk and Western, which represent actual operating conditions in tunnels with steam locomotives. We are also conducting tests at Lambert's Point pier where a series of samples are placed over a yard switching track, exposed to the smoke of locomotives and also salt air.

We hope this spring to install another set of samples in the Hackensack Meadows near New York, where the fumes of various chemical factories, and smoke from locomotives have a very severe action on conductors in that neighborhood. We want to see which of the alloys is best suited for conductors in this locality.

This report is submitted as information.

Vice-President John E. Armstrong:—It will be so accepted.

Chairman W. M. Vandersluis:—That concludes the report of the Committee.

Vice-President John E. Armstrong:—The Committee is excused with the thanks of the Association for their fine work (Applause).

## DISCUSSION ON WOODEN BRIDGES AND TRESTLES

(For Report, see pp. 997-1009)

(Vice-President John E. Armstrong in the Chair.)

Mr. H. Austill (Mobile & Ohio):—The report is found in Bulletin 364, page 997. It is largely a progress report.

Mr. Smith, the Chairman of the Sub-Committee on Revision of Manual, is absent, so I will report this series of proposed revisions.

In the 1929 Manual, page 458, under heading "Relative Merits of Open and Ballast Deck Timber Trestles," paragraph 2 now reads: "The principal advantages of the ballast deck trestle, when compared with the open deck type, are: Better protection against loss and damage and interruption to train service due to fire; superior track riding qualities; more satisfactory and safer appearance; greater serviceability, and better performance when subjected to overload; vastly less expensive to maintain."

The Committee recommends that the last line, reading "Vastly less expensive to maintain," be deleted, and I so move.

Vice-President John E. Armstrong:—You have heard the motion and the second. Is there any discussion?

Mr. B. R. Leffler (New York Central):—Why delete it? It is a fact or it is not a fact. Is the maintenance more economical or is it not?

Chairman H. Austill:—The Committee thought it was more economical, but not vastly so.

Mr. B. R. Leffler:—Perhaps "vastly" should be omitted, but I do not think we should omit the economics. If there are any merits, we ought to stand by them.

Vice-President John E. Armstrong:—Are there any further questions? Are you ready for the question?

Mr. H. M. Stout (Northern Pacific):—I move to amend the motion by eliminating the word "vastly".

Mr. B. R. Leffler:—I will second that motion.

Vice-President John E. Armstrong:—You have heard the amendment to the motion. The motion is that the words "Vastly less expensive to maintain" be deleted. The amendment is that only the word "vastly" be deleted. Is there any further discussion? Are you ready for the question? Those in favor signify by saying "aye"; opposed likewise. The amendment carried.

Chairman H. Austill:—In the 1929 Manual, page 458, the heading of the paragraph now reads: "Comparative Merits of Ballast Deck and Reinforced Concrete Trestles." The proposed amendment is to add the words "Creosoted Timber," making it read: "Comparative Merits of Creosoted Timber Ballast Deck and Reinforced Concrete Trestles."

Vice-President John E. Armstrong:—Is there any discussion on this? In order to expedite matters, we will discuss these items as we come to them and make a suitable motion at the finish to cover the lot. Is there any discussion on this change?

Mr. Theo. Doll (Santa Fe):—Is not the word "ballast" a noun instead of an adjective? I would suggest that we change it to "ballasted" deck so as to make it an adjective.

Vice-President John E. Armstrong:—The Committee accepts that.

Mr. I. L. Simmons (Rock Island):—Do I understand that these are to be reinforced ballasted deck concrete trestles? Concrete trestles are now being built without any ballast on them. I wonder if we had not better define what we mean. What does

the comparison take in? Does it consider that the concrete trestle is to be a ballasted deck?

Chairman H. Austill:—At the time this was adopted it was considered that a concrete trestle would be ballasted deck.

Mr. I. L. Simmons:—Should not there be a distinction made due to present practice?

Chairman H. Austill:—Would you suggest adding "ballasted deck" to the concrete also?

Mr. I. L. Simmons:—I would like to make a motion that "ballasted deck" be included, making it read: "Comparative Merits of Creosoted Timber Ballasted Deck and Reinforced Concrete Ballasted Deck Trestles."

Chairman H. Austill:—That is agreeable to the Committee.

Mr. J. C. Irwin (Boston & Albany):—I ask the question whether this is pertinent to what is in the Manual. We are trying to make a new heading. The question is, does the material in the Manual apply to untreated timber and creosoted timber as well? We have not before us the material in the Manual, and we are making a specific title on something that may have been entered in the Manual to include both treated and untreated timber at the time. While it is probably creosoted, I think it should explain that creosoted timber is what is referred to in this section of the Manual.

Chairman H. Austill:—That is the case. That is the reason for this proposed revision, to make the heading really fit what was adopted, is what the Committee had in mind at the time of the adoption.

Vice-President John E. Armstrong:—That revision is acceptable to the Committee.

Chairman H. Austill:—Page 458 of the 1929 Manual, paragraph 5, under the heading "Comparative Merits of Ballast Deck and Reinforced Concrete Trestles," the Committee recommends the deletion or removal of that paragraph, reading:

"(5) Notwithstanding the fact that the two materials are, with certain limitations, equally suitable for the construction of trestles, the use of concrete is more in accord with the theory of conservation of natural resources and industrial economy."

Vice-President John E. Armstrong:—Are there any comments?

Chairman H. Austill:—Page 461 of the 1929 Manual, we have a detail showing the use of lag screws, fastening of guard timber so as not to require the dapping of the guard timber. This was adopted before the standard plans which are also in the Manual, and it is therefore a duplication as this is shown on the standard plans. The Committee recommends that this sketch and plan be eliminated.

Vice-President John E. Armstrong:—Is there any discussion?

Chairman H. Austill:—Page 466 of the Manual, paragraph 13 reads:

"Caps shall be sized and brought to a uniform thickness and even bearing on piles or posts. The side with the most sap shall be placed downward."

The Committee recommends that this paragraph be eliminated.

Vice-President John E. Armstrong:—Is there any discussion, gentlemen?

Mr. B. R. Leffler:—I think that interferes with the paragraph as it now exists. In framing a timber structure, there is no more particular work than the framing of the caps and the stringers. If piles do not bear exactly on the under side of the caps, large crushing stresses ensue, with consequent deterioration of the under side of the cap. I think the original as it stands is first rate. I would not change it.

Chairman H. Austill:—The Committee felt that the first part of that paragraph was taken care of in other instructions, and primarily what they had in mind was the last sentence reading, "The side with the most sap shall be placed downward." From information available, after several years of study, the Committee felt that that was not proper construction.

For the benefit of the Association I will read a digest of replies to a circular that was addressed not to all railroads but to those that we thought we could get good information from. While many replies were the same, I have only listed here those that differ. The reason given for placing the sap down was less damage from fire when the timber ages. Practically everybody who favored that type of construction gave that reason. It was preferable to place the sapwood in such a way that the least proportion of sap would be in contact with the other members of the structure. With the sap up, it absorbs moisture and quickly starts decay. The reasons given for placing the sap up were: More natural position, and reduces checking; less accumulation of water entering timber through shakes and checks; better opportunity to inspect, trim, and reduce fire hazard; greater bearing resistance; more important to have full width of bearing on solid wood, on the under side than on the upper side, for a stringer or cap would tend to roll less with the flat bearing on the rounded surface than with the rounded bearing on the flat surface. If the cap were boxed heart, with pith nearer one face than another, it might have a check running from that face to the pith. If this face were placed up, it would allow the entrance and penetration of moisture, while if the sap face were up, it would be more likely to have several small checks than one large one. If the cap were side cut, it would check less and shiver up less with the sap side up.

Mr. B. R. Leffler:—I think the views on sap are all right for untreated timber, but I think the best practice in these days is to use treated timber. If that is the case, then the requirement pertaining to sap is useless. What I was after was to retain the better framing which required the caps to be framed so as to fit the tops of the piles. I think the Committee ought to enlighten the Association as to the practice of creosoting timber caps. The practice is extending; I think it is almost universal east of the Missouri River, perhaps not out in the Northwest. I think we ought to modify our recommendations to fit creosoted timber requirements.

Chairman H. Austill:—The Committee felt, from the best information we could get, that it made no difference in creosoted timber whether the sap were placed up or down, and the judgment of the man in the field should be taken as to how that particular timber should be turned.

Vice-President John E. Armstrong:—Is there any further discussion on this point?

Mr. B. R. Leffler:—I move that the question of cap framing be retained.

Vice-President John E. Armstrong:—What you have in mind is to omit at this time this proposed revision of the Manual, leave it as it is?

Mr. B. R. Leffler:—Yes, except that if the Committee has considered this question of sap location in view of treated timber, I am indifferent to it; I do not care which way the sap is put. But I think the framing should be retained. I make a motion to that effect.

Chairman H. Austill:—If Mr. Leffler will move to eliminate the last line instead of the entire paragraph, that would be agreeable to the Committee.

Mr. B. R. Leffler:—I will so move.

Vice-President John E. Armstrong:—Eliminate the words, "The side with the most sap shall be placed downward"?

Mr. B. R. Leffler:—Yes.

Vice-President John E. Armstrong:—Is there any further discussion? Those in favor will signify by the usual sign; opposed likewise. The motion is carried.

Chairman H. Austill:—Page 466, paragraph 19 of the 1929 Manual reads:

"Stringers shall be sized to a uniform depth at supports. The edges with the most sap shall be placed downward."

The Committee recommends the withdrawal of that entire paragraph. It will also be agreeable to the elimination of the last line instead of the entire paragraph.

Mr. B. R. Leffler:—Here again I contend for the retention of the first sentence and the elimination of the second. I think the stringers should be sized to uniform depth, and so on.

Vice-President John E. Armstrong:—The Committee has suggested that that be revised, Mr. Leffler, that the last line be omitted instead of the entire quotation. Is there any further discussion on this point?

Chairman H. Austill:—I move that with the previously adopted corrections and amendments, the proposed revisions of the Manual shown on page 998 be adopted.

Vice-President John E. Armstrong:—You have heard the motion and the second. Is there any discussion? Those in favor signify by the usual sign; opposed likewise. The motion is carried.

Chairman H. Austill:—Subject (2) Simplification of Grading Rules and Classification of Timber for Railway Uses. Mr. Hawley, the Chairman of the Sub-Committee, is absent. This is merely a progress report.

Subject (3) Overhead Wooden or Combination Wooden and Steel Highway Bridges will be presented by Mr. Hart, the Chairman of the Sub-Committee.

Mr. R. P. Hart (Missouri Pacific):—The report of Sub-Committee (3) will be found on page 999 of Bulletin 364. The main information presented this year for consideration is a table of sizes for piles to be used in highway overhead bridges. The Committee felt that the sizes provided in the 1929 Manual for piling for railway use were larger than necessary for highway bridges. This table is presented as information, with the thought that it may be recommended for inclusion in the Manual at a later date.

Vice-President John E. Armstrong:—The report will be so accepted.

Chairman H. Austill:—The remainder of this report is either progress or presented as information. There is nothing requiring the action of the Association. To expedite matters and save time, if it is agreeable, we will so report.

Vice-President John E. Armstrong:—Is this action acceptable? If so, the report will be accepted.

Chairman H. Austill:—I should like to call attention to two misprints. On page 1002, formula (8) should read "arc-tangent" instead of "tangent minus the parentheses." In formula (9) the line is left out between the  $L$  and the 2. It should be  $L$  over 2 minus 1.

$$(8) r_1 = \frac{WL}{2} - \left[ \sqrt{2} \tan^{-1} \left( \frac{L}{\sqrt{2}} \right) - \frac{W}{L} 2.3 \log_{10} \left( \frac{2 + L^2}{2} \right) \right]$$

Vice-President John E. Armstrong:—Gentlemen, this Committee is doing a large amount of work. The fact that they are only in position to report progress and make interim reports at the present time is an indication of the amount of work they have in hand which is progressing toward a conclusion.

The Committee is excused with the thanks of the Association (Applause).

## DISCUSSION ON MASONRY

(For Report, see pp. 957-996)

Mr. Meyer Hirschthal (Delaware, Lackawanna & Western):—The Masonry Committee presents its report as printed in Bulletin 364, beginning on page 957. Unfortunately, there occurred a misprint in some of the matter to be printed in Appendix A, which misprint will be pointed out to you and correction made by the Chairman of the Sub-Committee when presenting his report.

The Masonry Committee reports this year on six items of its assignment, Subjects (2), (3), (5), (6), (7) and (8), contained in Appendices A, B, C, D, E and F, and presents progress reports on the other assignments.

This year Committee (1), Revision of Manual, has no report because of the fact that it is awaiting a decision of the Joint Committee on Specifications of Concrete and Reinforced Concrete, which has reached a point in its deliberations where certain definite recommendations will be made, which will be contained in our next year's report, and on certain items which pertain to concrete specifications for buildings, which will then be included with a report of the Committee on Revision of Manual.

The first subject we do report on this year is that of assignment (2), specifications and principles of design of plain and reinforced concrete, contained in Appendix A. This report will be made by the Sub-Committee Chairman, A. N. Laird.

Mr. A. N. Laird (Grand Trunk Western):—The report of Sub-Committee (2), Specifications and Principles of Design of Plain and Reinforced Concrete is contained in Bulletin 364, pages 958 to 967 inclusive.

The portion of the report commencing at the middle of page 963, headed "Design and Construction of Reinforced Concrete Arches (Continued)" is a continuation of a report of this Sub-Committee on Specifications for Reinforced Concrete Arches. This portion of the report is directly related to the first paragraph on page 958, and in the printing it became disarranged. That portion should precede the subject-matter on Reinforced Concrete Trestle Design.

The first portion of this report which is designated as Section 8, is a continuation of the design section of the specifications. The sections dealing with the details of design and with construction requirements follow as Part III and Part IV. There is one misprint on page 965, the third line of the last paragraph. The last expression should read: "At the approximate one-fourth points of the span." With this change this portion of the report is submitted as information.

The President:—It will be so received. Is there any discussion on it?

Mr. A. N. Laird:—The portion of the Sub-Committee report commencing on page 958 headed "Section 2" in small type, and entitled "Reinforced Concrete Trestle Design—E-60 Loading" should have been designated as Section 1, for clarity in connection with the recommendations of the Committee. This portion of the report, consisting of the group of figures indicated from 1 to 7 inclusive, is submitted after having been presented to the convention last year as information and is submitted by the Committee for adoption as standard practice and for publication in the Manual.

I so move.

The President:—It has been moved and seconded to adopt the designs as shown, Fig. 1 to 7 inclusive, as recommended practice, and for printing in the Manual. In order to permit discussion, I will ask the Chairman to refer to each of these figures and give the members a chance to rise and discuss the subject, if they so desire.

Mr. A. N. Laird:—The order in which these figures are presented is not quite the same order which the Committee wishes to recommend for actual publishing in the Manual, but for convenience in discussion I will adhere to the order that they appear in the Bulletin.

Fig. 1 on page 958 deals with the design for single bent construction.

Mr. B. R. Leffler (New York Central):—If this is a 5-pile bent construction, no provision is made for lateral bracing. Is it the intention to let the cap and the piles take care of that in a rigid frame?

Mr. A. N. Laird:—The size of piling indicated is 16 in. They are reinforced piles. In the design it was the intention to provide for normal heights of trestle only, and in the case of extremely high trestles, additional construction in the shape of collars, and so on, would be required.

Mr. C. C. Westfall (Illinois Central):—I was under the impression there was a design in the Manual now for 18-in. concrete piling. I wonder if this is intended as a change from the Manual.

Mr. A. N. Laird:—The pile that is indicated as Fig. 5 is a 16-in. pile. There is no pile 18 in. in diameter now in the Manual. This 16-in. pile is a part of a specific design.

The next one, Fig. 2, deals with double bent reinforced construction. It is for use in long trestles for longitudinal stiffness.

The President:—Is there any discussion on this design?

Mr. A. N. Laird:—Fig. 3 at the bottom of page 959 indicates the end bent construction which is similar to Fig. 1 but with a slight extension of the bent cap and with the addition of a ballast wall.

The President:—Is there any discussion on this figure?

Mr. A. N. Laird:—Fig. 4 deals with the design for the slab, indicated as 16 ft. long, center to center of bents.

Mr. B. R. Leffler:—I do not like the cantilever action of the cap. It is a wide cap on a comparatively narrow pile bed, and under deflection there might be considerable load thrown out on the corner of the cap. It seems to me the cap should have some transverse reinforcement with a sliver or diagonal piece. I refer to the bearing directly under the slab.

Mr. A. N. Laird:—May I call attention to the design of the bent cap itself in Fig. 1, also in Fig. 2 and Fig. 3, which indicates such reinforcement in the form of lateral ties extending around the longitudinal reinforcement. I also call attention to the fact that the top of the bent is chamfered slightly, which will throw the point of bearing very close to the end of the slab.

Mr. B. R. Leffler:—That is true. I withdraw my remarks.

Mr. A. N. Laird:—On page 961, Fig. 5 deals with the design of the concrete pile itself. This is for a precast unit.

The President:—Is there any discussion on this design?

Mr. C. C. Westfall:—Back to my other point. I do not see why, if the Association recommends an 18-in. pile, the 16-in. pile should be given as a sample for the design. The question might arise whether a change of 2 in. in the size of pile might change the details of the cap.

Mr. A. N. Laird:—The size of pile indicated is predicated on E-60 loading. It is felt by the Committee that the 18-in. pile for a 5-pile bent is not necessary for this loading. In case the loading were increased to E-65 or E-70, then there would probably be a change in either the number of piles or the size of piles to compensate for that additional loading.

Mr. C. C. Westfall:—Is it the intent to change the Manual and put the 16-in. pile in in place of the 18-in.?

Mr. A. N. Laird:—There is no 18-in. pile in the Manual.

Mr. C. C. Westfall:—The 18-in. pile was designed for E-60 loading. My point is the A.R.E.A. 18-in. pile is standard, as I remember, for E-60 loading. That 18-in. pile was put in the Manual to take the place of the 16-in. pile originally put in there.

The President:—Mr. Westfall, will you please give the reference to the pile in the Manual that you refer to? It is my understanding that it has been removed from the Manual.

Mr. C. C. Westfall:—I am sorry, but I do not have the Manual with me. It may be that that has been taken out of the Manual. I thought possibly the Chairman would correct me if I was wrong.

Chairman M. Hirschthal:—It is my impression that the 18-in. pile had been in the Manual but was withdrawn at one of the meetings here three or four years ago. That is my recollection of that topic.

The President:—I think that is correct.

Mr. J. E. Willoughby (Atlantic Coast Line):—The 16-in. piling is sufficient for any purpose which the Committee has considered. We have not found it always sufficient for the protection of the reinforcement. After a number of years of use of the 16-in. piling, we have abandoned it for the 18-in. piling merely to get reinforcement deeper and farther away from the surface of the pile.

Mr. B. R. Leffler:—I do not think the Committee ought to stick to the E-60 loading. If these diagrams were gotten up on the E-60 basis, I think it was a mistake. There are plenty of locomotives for these short panels, in particular, that are close to E-70. I do not like the idea of a recommended practice based on E-60 loading. That makes it too small if we are considering reinforced concrete as reasonably permanent.

Mr. A. N. Laird:—Mr. Leffler, the E-60 loading was adopted for this particular design because it was felt there were many locations where that loading would still be applicable and for direct comparison with the creosoted timber pile trestle of the same loading. It is the intention of the Committee to proceed with the preparation of similar designs for the heavier loading.

Mr. B. R. Leffler:—I noticed, however, that the Committee on Wooden Bridges and Trestles has given a tentative specification for E-70, and they have a table worked up for that loading.

Mr. A. N. Laird:—It is the intention to proceed at once to submit for the next convention tentative designs for the E-70 or E-72 loading. That point has not been definitely decided.

Fig. 6 deals with the details of trainmen's walks. There are alternate constructions indicated, both structural steel with timber plank, and reinforced precast concrete.

The President:—Is there any discussion on these designs?

Mr. A. N. Laird:—Fig. 7 on page 963 indicates the special construction where multiple track trestles are to be used.

The President:—Is there any discussion on Fig. 7? Are you ready for the question? The question is on the adoption as recommended practice and for printing in the Manual, of these seven designs. All those in favor will say "aye"; contrary. The motion is carried.

Chairman M. Hirschthal:—This subject, of course, will be continued.

The next item to be presented is assignment (3), Appendix B, Progress in the science and art of concrete manufacture, to be presented by Mr. L. W. Walter, Chairman.

Mr. L. W. Walter (Erie):—The report of Sub-Committee (3) is identified as Appendix B of the Masonry Committee's report and appears on pages 967 to 975.

Summarizing this report briefly, the first section deals with vibration in placement of concrete.

In the present state of the art, vibration may be defined as a method of assisting concrete into place by increasing its mobility through rapidly applied impulses.

Vibration as now practiced may be divided into five kinds as to method:

1. Vibration of forms.
2. Internal vibration.
3. Vibration of reinforcement, structural steel members, or track assemblies.
4. Platform vibration.
5. Unit vibration.

A short description of each method is given, as are also some of the advantages and disadvantages associated with their use, together with some precautions suggested. This is followed by an abbreviated bibliography on high-frequency vibration of concrete.

The second section of the report deals with ready mixed concrete, which is divided into two classes, namely, central mixed concrete and transit mixed concrete, differing as their names imply. The report lists some of the advantages and disadvantages associated with the manufacture and use of each. Your Committee would call particular attention to some of the precautions to be taken in their selection and use.

Reference is made in the report to the tentative specifications for ready mixed concrete, A.S.T.M. C-33T. Here I will state that a correction should be made in the second line on page 974. The serial designation should read C94-33T instead of C-33T.

The third section of the report deals with segregation of materials in concrete. These are classified as of three types, namely, segregation of materials in finely divided state or of low specific gravity; segregation of water and its incorporation in concrete in parts of structures in quantity in excess of that designed for the mix, and separation of mortar from coarse aggregates. A high degree of workability and stiff consistency are essential if segregation is to be minimized. The ways of securing both are described in the report. This report is presented as information only.

I move that it be received as such.

The President:—It will be so received. Is there any discussion on this report?

Chairman M. Hirschthal:—This subject is also to be continued.

The next assignment is (4), contact with Joint Committee on Standard Specifications for Concrete and Reinforced Concrete. My report is verbal. There has been a change in the representation of the A.R.E.A. on this Committee by virtue of the resignation of Mr. Richardson from the Masonry Committee, he being replaced by Mr. L. W. Walter as representative of the A.R.E.A.

The proceedings of this Committee have reached a point where, during the current year, we expect to have final specifications. Most of the assignments have been made to sub-committees of the Joint Committee, and these specifications will then be included in the Masonry Committee's report as revisions of the Manual or changes in the art, as the Committee will decide in its deliberations.

Subject (5) is foundations, and will be presented by Mr. D. B. Rush, Chairman of the Sub-Committee.

Mr. D. B. Rush (Robt. W. Hunt Company):—You will recall that we have worked on this subject several years. We first were instructed to draw up a specification covering the original research in the character of soil, and that work was published in Vol. 31, page 1176; next, we were asked to study a method of applying this research practically to the design of foundations. The results were published in Vol. 33,

page 650. Then we come finally to a general specification for the construction of foundations that could be referred to in writing detailed specifications for bridge structures, or could, in itself, be taken as a general specification. What we have written this year is not at this time for insertion in the Manual but for information. It is not intended to be a textbook. You know, there has been a good deal of criticism about some of the specifications in that respect. It is just supposed to contain the necessary general clauses that you gentlemen can well fill in with the details you desire, for the particular structure in hand.

The Committee, as I now remember it, was unanimous in the opinion that all three, or any one of the present sections of the specification must be applied by some one of you Bridge Engineers who are competent to do it. That does not mean by an inspector. That means by a man who is competent to do the investigating work, to design a structure and superintend the construction. Several new and, what we believe, interesting features have been inserted. Personally I cannot recall ever having seen before any definite recommendation of a competent body of men on any method of determining soil pressures. The Committee has gone on record as in general approval.

In the second place, I can remember no instance where any of the various methods of determining soil pressure have been approved by any body of men, and any method worked out for their application to design. In fact, they are generally so involved that only a very limited number of men would be able to use them.

At the very start of the general specification we made a change in the definition. The first two definitions are printed here and are presented for adoption and inclusion in the Manual. I should like to read those to you:

"FOUNDATION.—The natural material which supports the structure, and its loads, whether strengthened or not by the use of piles or other means to secure adequate bearing.

"SUBSTRUCTURE' refers to that part of the structure which supports the superstructure and its loads."

I might tell you in this connection that we had a definition of superstructure, but this only being a Sub-Committee on Foundations, that was left out. You will see that this makes quite a change in the ordinary, accepted idea. If you approve of it, we now move for its adoption and inclusion in the Manual.

The President:—It has been moved and seconded that these two definitions at the top of page 976 be adopted and printed in the Manual. It is not customary, as announced before, to discuss on the floor any particular features of definitions as may be termed in the nature of editing, but if there is anything materially wrong with these definitions, we would like to know it.

Mr. F. P. Turner (Norfolk & Western):—My conception of a foundation, as you described it, is the earth or rock that supports the entire substructure. That has always been described in textbooks which I have followed as the foundation-bed, not the foundation. The foundation is the material you place on top of the foundation-bed. This is a part of the substructure, and the neat work above is also a part of the substructure. I thought I would bring that to your attention.

Mr. D. B. Rush:—You are quite right. That is why I told you that this is a change. May I ask how you would differentiate between the foundation and the substructure?

Mr. F. P. Turner:—I think the foundation is really a part of the substructure; the neat work, which usually extends below the water level or below the ground, is another part of the substructure. That is my definition.

Mr. D. B. Rush:—We have made a change, and we want to know if you will adopt it. We believe that this is very much better.

Mr. F. P. Turner:—From my own personal point of view and understanding, I prefer the old definition, because it seems to me that you are describing something as a foundation which already existed, whereas you usually place the foundation as a part of the construction work.

Chairman M. Hirschthal:—It was just because of this type of misconception or misunderstanding or ambiguity that we decided to define foundation and substructure as we have. In the discussions of the Masonry Committee we found that various members understood a foundation your way and others understood it our way. We decided that once it is understood either way it will be generally understood that way. We therefore decided to define it as we do in the Bulletin and ask you to accept it that way so there may be a general understanding of the definition as it has been presented.

The President:—Are you ready for the question? All those in favor will say "aye"; contrary. The Chair is uncertain. I will have to ask for a division of the vote. All those in favor will please stand; those contrary-minded will stand. The vote is practically two-thirds in favor of the motion, only a majority is required. Therefore the motion is carried.

Chairman M. Hirschthal:—Just one more word. What Mr. Turner referred to as the foundation and neat work is generally referred to as a footing. That led to the misunderstanding. We decided not to differentiate between a footing and the rest of the substructure. That is how this definition arose.

Mr. D. B. Rush:—That is a method of determining whether or not you use piling in your foundation. The thing everybody wants to discuss is the classification of materials. They are all down here as we have classified them. Bear in mind that that is the classification of a committee of Bridge Engineers but not a committee of contractors or people who are disinterested. That is what the consensus of this Sub-Committee is. What we want you people to do, if you will, is to write us all of the objections you have, criticisms, or approval, or anything else, on our classification of materials and be assured that it will be taken up before the next meeting.

I do not believe there is any need to read over this entire proposition, but we want you to write us, and then we will start on the draft of the final section of these specifications covering the construction of the substructure.

The President:—The balance of the report will be received as information.

Chairman M. Hirschthal:—I regret very much that it was necessary to curtail the discussion on the subject of Foundations which we feel is a very, very important subject. I want to urge the members to send their comments, either adverse or favorable, criticisms and suggestions, to the Chairman of the Sub-Committee to aid him in collecting all this data in a revision of the specifications that have been drawn up thus far, if necessary.

The next subject is assignment (6), Appendix D, Tentative Specifications for Lining Railway Tunnels with Concrete. Mr. G. F. Eberly, Chairman of the Sub-Committee will present this report.

Mr. G. F. Eberly (Baltimore & Ohio):—The subject-matter of this report will be found on pages 979 to 983 inclusive, Bulletin 364. As you know, this subject is under the assignment, methods and practices of lining and relining tunnels.

This year we have prepared a tentative specification for lining railway tunnels with concrete, which is the beginning of a number of specifications for lining tunnels with

various materials. We also intend to determine the best material for the lining of railway tunnels for steam operation and for electrical operation.

Are there any questions on these tentative specifications? I will be very glad to answer them. If not, it is submitted as information.

The President:—It will be so received.

Mr. B. R. Leffler:—I would suggest that in Section 10 a statement be made to the effect that the 5.5 gallons of water covers any water that may be found in the aggregate. I think the Committee intends to have it so.

Mr. G. F. Eberly:—I think that is well stated, and we will make that correction.

Chairman M. Hirschthal:—This subject is also to be continued.

The next subject is that contained in Appendix E, (7) pneumatically projected concrete, to be presented by Mr. T. L. Condron, Chairman of the Sub-Committee.

Mr. T. L. Condron (Consulting Engineer):—The report of this Sub-Committee is found in the same Bulletin referred to, on page 984. The assignment of specification for pneumatically projected concrete has been covered by writing a tentative specification, and the word "Shotcrete" has been used as a brief descriptive form, not copyrighted, so that it could be readily used in specifications and on plans where it was desired to indicate the material to be used. The specification is presented for information. If there is anything you wish the Committee to add or any suggestions, we will be glad to have them.

Mr. B. R. Leffler:—I suggest that the Committee investigate the question of anchorage of the Shotcrete concrete on old concrete so as to be sure that the Shotcrete will be held to the old concrete. That is particularly important in ceiling work, overhead work, and the under side of arches. It is a question that has not been presented or discussed before any technical body that I know of.

Mr. T. L. Condron:—I think there are in the Manual paragraphs on that feature in connection with the repair of concrete structures. It would hardly seem necessary to repeat them in this specification.

Mr. B. R. Leffler:—That will take care of the matter.

Chairman M. Hirschthal:—This subject is also to be continued.

The next assignment is that contained in Appendix F, design of expansion joints involving masonry structures. Mr. C. A. Whipple, Chairman of the Sub-Committee, will present this report.

Mr. C. A. Whipple (Chesapeake & Ohio):—This report appears on page 986 in Bulletin 364. During the last two years the Committee collected from a number of carriers plans covering various types of joints involving masonry structures to meet various conditions. Last year it submitted sketches appearing under Appendix E, Bulletin 353, page 599, as information.

This year the Committee has made further study of the joints submitted, with criticisms and suggestions of the various details, and offers basic principles to be observed in determining the details of expansion joints, suggesting a classification of joints applying to both longitudinal and vertical expansion joints, with general discussion of the details.

Appearing on pages 987, 988 and 989 are comments covering the joints submitted. Sketches of the joints appear on pages 990, 991, 992, 993, 994, 995 and 996. It is recommended that the report be received as information and the subject be continued.

The President:—It will be so received.

Chairman M. Hirschthal:—Assignment (9) was for a review of the specifications for overhead highway bridges as prepared by the Association of State Highway Officials in order to discover some more rational means of design which will result in greater economy. Such review has been made during the year but it is not in such shape as to

be presented as a report, and the subject will be continued next year when we hope to give you a report.

That concludes the report of the Masonry Committee.

The President:—The Committee on Masonry has our thanks for their very excellent report, and they will now be excused (Applause).

## DISCUSSION ON GRADE CROSSINGS

(For Report, see pp. 561–577)

Mr. J. G. Brennan (New York Central):—The report of Committee IX—Grade Crossings is shown in Bulletin 361, page 561. On the first assignment, Revision of Manual, including:

(a) Further study of the proper lighting of the base of signals where located in the center of highway, the Committee reports progress and recommends that the subject be continued.

(b) Further study and recommendation in regard to center-road installation of flashing light or wig-wag type of signals. The Committee reports progress and recommends that the subject be continued.

Appendix B, economic aspects of grade crossing protection in lieu of grade separation. It is the recommendation of the Committee that the subject be continued. Considerable work has been done on this assignment, but the Committee is not ready to submit a report.

Appendix C, recommend standard specifications for street crossings over railway tracks, both steam and electric. Mr. V. R. Walling, Chairman of the Sub-Committee, will present the report.

Mr. V. R. Walling (Chicago & Western Indiana):—This subject will be found in Bulletin 361, pages 562 to 568 inclusive, Appendix C, recommend specifications for highway crossings at grade over railway tracks, both steam and electric, collaborating with Committee I—Roadway, and with American Society of Municipal Engineers and American Transit Association.

This year four specifications are submitted for your consideration, namely:

(1) Specifications for preparation of track structure, width of crossing and approaches for construction of street crossings over railway tracks.

(2) Specifications for the construction of rail type street crossings.

(3) Specifications for the construction of wood plank street crossings.

(4) Specifications for the construction of highway crossings surfaced with oil processed gravel.

These have been submitted to the Roadway Committee, American Society of Municipal Engineers and American Transit Association, with whom your Committee has been instructed to collaborate, and no exceptions have been taken.

In this connection, there are three members of the Roadway Committee delegated to collaborate with this Committee. These members are likewise members of the Grade Crossings Committee, so that the contact is direct. We have had very many useful suggestions from them, which have been incorporated in the specifications.

As regards the collaboration with the American Transit Association, that is being carried on by your Sub-Committee Chairman with Mr. Archambault, who is Chairman of the Standing Committee of Ways and Structures of that Association. This is being carried on both personally and by correspondence, and is being satisfactorily handled.

We have also furnished the American Society of Municipal Engineers copies of all the data that we have prepared to date.

Your Committee is recommending the adoption as recommended practice and for publication in the Manual the first three specifications and submitting as information No. 4.

On page 563, specifications for preparation of track structure, width of crossing and approaches, for construction of street crossings over railway tracks—I move the adoption of this specification as recommended practice and for publication in the Manual.

The President:—You have heard the motion. Is there any discussion?

Mr. J. B. Jenkins (Baltimore & Ohio):—I should like to have an explanation as to just how the Committee will accomplish what is called for in the first sentence on page 564, and also the second sentence. In that connection I would like to call to mind the rule made by a single track road, prohibiting facing point switches, and also a law passed by a certain state that when two trains met at a grade crossing, neither should proceed until the other had cleared the crossing.

Mr. V. R. Walling:—I presume you refer, Mr. Jenkins, to the paragraph at the top of the page: "Rail shall be so placed that there will be no rail-joints within the crossing, and with joints preferably located not less than one-half rail length from the crossing."

Mr. J. B. Jenkins:—I should like to know how that is physically possible.

Mr. V. R. Walling:—It would depend to some extent, of course, upon the width of the crossing and the length of the rail. It seems to me that it would be perfectly feasible, for certain width crossings and certain lengths of rail, for that to be accomplished.

Mr. J. B. Jenkins:—Suppose you have a crossing 20 ft. wide and have a rail, say, 60 ft. long and do not have any joint within the crossing. One of the joints certainly must be less than half the rail length away from the crossing, probably both joints.

Mr. V. R. Walling:—It seems to me we qualify that by the second clause: "If, because of the width of the crossing, this is not practicable, the rail ends shall be welded to form continuous rail through the crossing."

Mr. J. B. Jenkins:—That would not accomplish it.

Mr. V. R. Walling:—May I have your suggestion?

Mr. J. B. Jenkins:—I would eliminate "and with joints preferably located not less than one-half rail length from the crossing." It is a physical impossibility to so locate them. I would eliminate the first half of the second sentence and substitute: "If the rail ends necessarily fall within the crossing, they shall be welded to form continuous rail through the crossing."

Mr. V. R. Walling:—We will accept that change, Mr. Jenkins.

The President:—The question then is on the motion to adopt this specification as recommended practice, with the change suggested by Col. Jenkins.

Mr. Meyer Hirschthal (Lackawanna):—I have just one little suggestion on paragraph 2. I am wondering whether it would not be preferable to simply say that proper drainage shall be provided at all crossings, cutting out the argumentative part. I do not think it is essential to put that into the specification. I suggest that paragraph 2 simply read: "Proper drainage shall be provided at all crossings." If you want to put in that it is a requisite, say "as it is a requisite," rather than putting the argumentative part first.

Mr. V. R. Walling:—We rather prefer it the way it is set up there, making a positive statement, of course, which is generally accepted, that a requisite for good track is proper drainage, and this shall be provided at all crossings.

Mr. Meyer Hirschthal:—I do not disagree with you that it is a requisite, but I do not believe that that part belongs in the specification.

Mr. V. R. Walling:—You want to have that read: "Proper drainage shall be provided at all crossings?"

Mr. Meyer Hirschthal:—Yes.

Mr. V. R. Walling:—We accept that.

The President:—Are you ready for the question to adopt the specifications with the two changes accepted by the Committee? All those in favor will say "aye"; contrary. It is carried.

Mr. V. R. Walling:—Page 564, (2) specifications for the construction of rail type street crossings—I move the adoption of this specification as recommended practice, to be published in the Manual.

The President:—It has been moved and seconded that we adopt this specification, (2), for the construction of rail type street crossings. Is there any discussion? All those in favor will vote "aye"; contrary. It is carried.

Mr. V. R. Walling:—Page 565, (3) specifications for the construction of wood plank street crossings—I move the adoption of this specification as recommended practice, to be published in the Manual.

The President:—It has been moved and seconded that we adopt specification (3). Is there any discussion?

Mr. J. C. Irwin (Boston & Albany):—On page 565, under materials and installation, it starts off with, "It is recommended that." Is that a necessary term in specifications? Could not you start the sentence with "Creosoted planking and shims", etc.?

In general, I would raise the question in a great deal of our work as to whether it should be approved for the Manual the first time it is presented. My experience has been that the Committee puts it up in what it considers the best form for action. It does not lose anything by seasoning for further discussion through another year. However, the Committee has recommended this. I would not raise a particular point on that except that I think we should all exercise a little caution in hurrying things through to the Manual if there has not been plenty of opportunity to read and study them. In this case my specific question is whether "it is recommended" is a suitable phrase for a specification.

Mr. V. R. Walling:—Our thought in that connection was this: We follow that up by stating "The accessibility of the various species of wood may determine the kind of timber and the kind of treatment, if any, that is most economical for use by an individual railway." Inasmuch as the railroads traverse such an enormous section of the country, in which many different kinds of wood are to be found, it may be that some road would desire to use a material not to be treated. We leave it open but recommend that creosoted planking shall be used. We do not make it mandatory. We prefer to leave it as it stands.

Mr. C. W. Baldrige (Santa Fe):—It seems to me that the Committee has one word wrong in the third from the last paragraph of this article, where it provides for planking the full length of the pavement, that is, a buffer plank between the railway crossing and the pavement. It seems to me that should read "the full *width* of the pavement" rather than "the full *length* of the pavement."

Mr. V. R. Walling:—I did not get that reference.

Mr. C. W. Baldrige:—On page 566, in the third paragraph from the bottom of this specification, it reads: "If pavement beyond the track is of concrete, a space of one inch shall be provided between the edge of planking and the pavement. If pavement is of construction other than concrete a 4 in. by 18 in. creosoted timber header shall be placed on edge the full length of the pavement", etc.

Mr. V. R. Walling:—You are right. That should be "width." We stand corrected.

The President:—Are you ready for the question? The question is on the adoption of specifications for the construction of wood plank street crossings. All those in favor will say "aye"; contrary. It is carried.

Mr. V. R. Walling:—Page 566, (4) specifications for the construction of highway

crossings surfaced with oil processed gravel. This specification is offered at this time as information.

The President:—It will be so received

Mr. V. R. Walling:—It is the recommendation of the Committee that this subject be continued for further study and the preparation of specifications for other types of street crossings.

Chairman J. G. Brennan:—The next subject is (4), relative economy of different types of highway grade crossings, Appendix D, page 568. Mr. F. D. Batchellor, Chairman of the Sub-Committee, will present the report.

Mr. F. D. Batchellor (Baltimore & Ohio):—This report is shown on pages 568 to 573 inclusive. On page 571 we have given suggestions for determining what type of crossing is the most economical for any particular crossing.

On page 573 in the summary statement the average life of concrete planks should be 17.5 years instead of 13.5 years. This report is offered as information.

The President:—Is there any discussion? The report will be received as information.

Chairman J. G. Brennan:—The next subject is (5), proper vertical curves on highways for grade separation projects. Mr. E. R. Lewis, Chairman of the Sub-Committee, will present the report.

Mr. E. R. Lewis (Michigan Central):—The report appears in Appendix E on pages 573, 574 and 575. The tendency of present practice of highways is to treat the sag curve in terms of the vision curve at the top of the grade. The Sub-Committee received very helpful response from the highway authorities of every state in the Union and all the various provinces of Canada to requests for details of present practice. The sag curve, especially, seems to be too generously lengthened. It is recommended that depression or elevation of highways required for separation from railroad grades be effected with the minimum of vertical curvature required for safety and utility.

It is further recommended that the foregoing be approved and published in the Manual. I so move.

The President:—The motion is on the adoption and inclusion in the Manual of Appendix E. Is there any discussion? All those in favor will say "aye"; contrary. It is carried.

This motion is carried. The Chair, however, would recommend to the Committee on Manual that they give consideration to the form in which this report is presented. I believe it needs some editing.

Chairman J. G. Brennan:—Subject (6), investigate the use and report on the merits and economy of the "Stop-and-Go" type of signal with red and green illuminated aspects, as a protective device at highway-railway grade crossings, under usual conditions and special conditions. This report is shown on page 575 under Appendix F.

It is recommended that the following conclusion be approved and that the Joint Committee on Grade Crossing Protection, A.R.A., be notified of such conclusion.

"'Stop-and-Go' signals should not be used for the protection of railroad-highway grade crossings where they are operated exclusively by the passage of trains, and their use should be confined to special locations where their observance can be enforced by police power."

I so move.

The President:—The motion is to adopt that conclusion. Are you ready for the question? All those in favor will say "aye"; contrary. It is carried.

Chairman J. G. Brennan:—That concludes the report of the Committee.

The President:—The subject of grade crossings and its various ramifications is one of the important problems before the railroads. This Committee has done very good work, and we extend our thanks, and they are now excused (Applause).

## DISCUSSION ON RIVERS AND HARBORS

(For Report, see pp. 677-697)

Mr. W. C. Swartout (Missouri Pacific):—Committee XXV—Rivers and Harbors is unique among the standing committees of the American Railway Engineering Association in that it consists of two separate and distinct committees, each having its special work and functions to perform, the Committee on Rivers and Harbors, and the Special Committee on Engineering Research, Inland Waterways and Intercoastal Canals.

The Committee on Rivers and Harbors is a scientific engineering research committee like the other committees of the Association.

The Special Committee on Engineering Research, Inland Waterways and Intercoastal Canals is for the purpose of studying the growth of the closer relationship between waterways and railways which we have witnessed during the recent years and perhaps handling, with public authorities, situations which may come up affecting these relationships. For the purpose of facilitating the work of this committee, the country is divided into nine zones, with a section of the committee for each zone, having its Chairman. These sectional committees, of course, handle questions peculiar to their zones.

The two committees are working and will work in close alliance on all waterways and related problems, according to a definite policy of correlation.

The report of Committee XXV will be found in Bulletin 363, page 677. We present reports on eight subjects and report progress on three subjects.

Sub-Committee (1), Revision of Manual, Mr. E. H. Roth, Norfolk and Western, Chairman. Mr. Roth is unable to be present, but, as a matter of information, we have gone over the Manual of 1929 and have found that it contains nothing that pertains to our Committee. There is, however, information in Supplements to the Manual as follows:

Bulletin 327, pages 92 to 95; Bulletin 337, pages 99 to 110; Bulletin 347, pages 75 to 83.

If on further study of these portions of the Manual, we find that revisions or suggestions are in order and should be made, appropriate recommendations will be made to the Association.

Subject (2), Definitions of Terms. The Committee this year presents thirty-one definitions of terms relating to Rivers and Harbors, as a matter of information, with the request that the members advise the Committee of any criticisms or comments. Your Committee has enlisted the cooperation of the Chief Engineer of the United States Army and of the similar branch of the Canadian government in the preparation of these definitions.

Possibly the most important definition presented this year is "Economic Justification." The definition as printed is not entirely satisfactory to the Sub-Committee and, of course, not to the General Committee. As this is a far-reaching definition and one fraught with possibilities of the utmost gravity, the Committee hopes that the membership will favor it with any comments they may have.

Appendix C, specifications for the construction of the several types of river bank protection in common use. This was prepared by the Committee of which Mr. P. J. McCarthy, of the Kansas City Southern, is the Chairman. The Committee is offering this specification for the information of the Association but we desire to retain jurisdiction over it because it requires editing and changes in several important respects. However, it is open to discussion if any of the members feel so disposed.

The President:—Is there any discussion on Appendix C? The Chairman of the Committee invites discussion.

Mr. F. L. Nicholson (Norfolk Southern):—I have carefully reviewed this specification, and it is one that goes into detail very minutely. It is a very valuable specification. It reflects considerable credit upon the Committee that prepared it. If the Committee had stopped at specifications covering materials and labor, I think they would have done a splendid work that could have been endorsed without much discussion. But it seems to me that they have gone beyond the bounds of specifications and have gotten into that of contract forms. Sections 1 to 3 and Sections 11 to 15 are not specifications.

We have a Committee on Contract Forms, which Committee recognizes always that there are times that a standard form will not apply and at times it is necessary to draw a special contract form. In order to meet such conditions, there has been provided coordination between the Committee on Contract Forms and the committee preparing specifications, in order that a form suitable for the special purpose may be prepared.

I should like very much, as this form is presented for discussion and for further consideration, to have the Committee take under advisement the omission of all of the paragraphs bearing on a construction contract. I make this point particularly because on yesterday we had a similar condition. In the report that was made by the Buildings Committee, they outlined five subjects for future handling, submitted to the organization for study and criticism. At the same time they submitted for approval and inclusion in the Manual a subject that was not in any of the Bulletins in the hands of the members but appeared in a Bulletin a year ago. I venture to say that not five per cent of the members who voted for inclusion in the Manual had the matter before them or had read it. What is there to prevent these five subjects that have now been submitted to us for study during the year, from being submitted in a similar manner at the next convention, and we will have no Bulletin before us from which to decide, but must act on faith alone?

My belief is that, in the consideration of any subjects for inclusion in the Manual, they should be in the hands of the members at the time they vote. I recognize that it was an economy measure, probably, that prompted its omission from the Bulletins in use today. In order that you may know that the objection now raised is justified, I want to refer you to page 540 of Bulletin 361. In the Specifications for Buildings for Railway Purposes, Steel Chimneys—Welded and Genuine Wrought Iron Chimneys, here is how the term "General" reads, which might mean much or little:

"The contractor shall completely design and shall furnish all labor, material, tools and equipment, and construct a steel chimney of the height and diameter shown on drawings and as specified. The chimney shall be either self-supporting, guyed or stayed as shown on drawings and as specified."

I question whether this organization desires to go on record with Manual matter that we shall require the contractor to design a chimney or any other structure. If such service is required, it is a matter for special contract and not for specifications nor should it be a recommended practice.

The President:—Mr. Nicholson, the Committee will consider your suggestion. You are discussing a matter that was up yesterday. Your point is well taken, and the Committee will take that matter into consideration.

Mr. J. C. Irwin (Boston & Albany):—In that connection in this immediate case, I talked with Mr. Swartout this afternoon and pointed out these difficulties. He had already agreed to take it under advisement. But as Chairman of the Committee on

Outline of Work, I should make it clear that specifications as defined in the Manual are that part of the contract describing the materials for the details of construction, and most of our committees have been able to confine themselves to that, leaving the agreement provisions with the Contract Committee.

I have been satisfied that Mr. Swartout, in this case, would correct that throughout the year.

Chairman W. C. Swartout:—Subject (5), types of bulkheads, jetties and seawalls, giving cross-section of each and stating the purpose which they serve, including comparisons of first cost, service life and maintenance cost of the various types. Mr. W. G. Brown is Chairman of the Sub-Committee and will present the report.

Mr. W. G. Brown (Florida East Coast):—A brief statement of Sub-Committee (5), which was assigned the study of types of bulkheads, jetties and seawalls, is shown under Appendix D on page 683 of Bulletin 363.

Much valuable data has been collected which, with additional data to be secured, we will study and assimilate into a comprehensive report this year. With this in view your Committee can now only report progress, with a request that the subject be continued.

The President:—The subject will be continued.

Chairman W. C. Swartout:—Subject (6), types of fender systems for protecting wharves and recommend suitable uses for each, including comparisons of first cost, service life and maintenance cost of the various types. Mr. Benjamin Elkind, of the Erie, is Chairman of the Sub-Committee and will present the report.

Mr. Benjamin Elkind (Erie):—The report of this Sub-Committee is on pages 683 to 688 of Bulletin 363. This report explains the purpose of the fenders and the three general types used—fixed, spring, and floating.

The report briefly describes the various kinds of fenders in use in different sections of the country and is illustrated by Fig. 1 to 7 on pages 685 and 686 of the Bulletin. The report covers only a part of the assignment and will be continued this year. The report is offered as information.

The President:—It will be received as such.

Chairman W. C. Swartout:—Subject (7), warehouse piers, coal and ore piers, car float piers and others, with recommendations as to the type suitable for use under varying conditions, including comparisons of first cost, service life and maintenance cost of the various types. Mr. R. C. Young, of the Lake Superior & Ishpeming Railroad, is Chairman of this Sub-Committee. He has been kept away from the convention by serious illness. Mr. Young, as you know, is one of the old warhorses of the Association and takes a lively interest in the Association and is assiduous in his work on committees.

In presenting his report, he sent me the following letter which I will read:

"On pages 688 and 689 is an account of the development of iron ore loading on the Great Lakes, with a brief general description of the modern iron ore loading docks now in use.

"At the bottom of page 689 and on page 691 is a description of the coal loading piers on the Atlantic Seaboard at and near Norfolk, Va., also grain elevators in the same vicinity.

"On page 690 is a table showing dimensions and capacities of the iron ore loading docks on the Great Lakes, which table is compiled and corrected each year by the Engineering Department of the Duluth, Missabe & Northern at Duluth.

"On page 692 is a brief general description of the coal and iron ore unloading docks and the crushed stone loading docks on the Great Lakes, followed by some comparative estimated construction and maintenance costs of timber, concrete and steel docks as of the year 1911, expressed in percentages.

"Near the top of page 693 is a brief description of coal and ore piers on the Pacific Coast.

"Your Committee has not attempted to show any sketches of designs but submit on page 693 a bibliography of the principal docks described above with greater particularity."

We submit this report as information, with a request that it be continued for further study and report.

The President:—It will be so considered.

\* Chairman W. C. Swartout:—That brings us down to Subject (10), economic principles involved in clearances over navigable waterways. Mr. R. H. Ford, of the Rock Island Lines, is Chairman of this Sub-Committee, and I will ask him to present the report of the Sub-Committee.

Mr. Robert H. Ford (Rock Island):—This is a progress report on what your Committee considers to be a fundamental principle of the economics of land transportation. To the end that an expression of the Association may be obtained for the guidance of our Committee, the following resolution is offered:

*"Resolved, That this Association is in accord with the principles as set forth in this report of the Committee on Rivers and Harbors on economic principles involved in clearances over navigable waterways, and which in effect are:*

*"That proper clearances for navigable streams are those which will not unduly interfere with the operation of either land or water transportation, cause unwise expenditures to be made for physical readjustments, or place burdensome restrictions on their future expansion. There must be an economic balance in the interest of both forms of transportation."*

I move the adoption of the resolution.

Mr. Albert Reichmann (American Bridge Company):—In view of the fact that the cost of all large bridges, whether built with public funds or by public utility corporations, must be borne by the public, I believe this resolution should be adopted and I therefore second the motion.

The President:—You understand that the procedure of action on these reports is laid down by the general rules. This is a little bit out of the ordinary, but, with the general consent of the convention, the Chair will entertain that motion. Do I hear any objections to it? All right, the motion is before you. Is there any further discussion? All those in favor will signify by the usual sign "aye"; contrary. It is carried.

Chairman W. C. Swartout:—Subject (11), cost to railways for construction, maintenance and operation of bridges over navigable waterways. Mr. F. E. Morrow, Chief Engineer of the Chicago & Western Indiana, is Chairman of this Sub-Committee. I will ask him to present the report of the Sub-Committee.

Mr. F. E. Morrow (Chicago & Western Indiana):—The subject of this report is cost to railways for construction, maintenance and operation of bridges over navigable waterways. This subject is different from most reports presented to the Association, in that it deals with the subject of what is considered an inequity in the present Federal statutes, and the determination of what is considered fair and equitable principles upon which our Federal statutes should be based.

No doubt all of the members of this Association are familiar with the fact that the obligation of constructing, maintaining and operating bridges over navigable waterways is now imposed almost entirely on the party or agency which makes the crossing over the waterway. Also, that all continuing obligations to make alterations and changes in such structures and the continued maintenance and operation of such bridges as altered or changed are likewise imposed upon the party or agency making the crossing over the waterway.

It is the view, as set forth in the report, that there are certain obligations which should rest, under certain conditions, upon the agency which provides and maintains the

waterways. Your Committee has arrived at the following conclusions as to principles which it believes to be equitable, and which should govern in providing funds for the construction and maintenance and operation of bridges, including approaches thereto, over navigable waterways:

"1. Any agency providing facilities for land transportation, when bridging a navigable waterway in its natural state, an improved waterway, or an artificial waterway, should assume the expense (but not more than) of constructing, maintaining and operating the bridge and other collateral facilities reasonably necessary to permit the use of such waterway in its condition at the time the crossing is made.

"2. Where an artificial waterway is constructed across existing land transportation routes, the governmental authority in charge of and providing the funds for the waterway project should bear the entire expense of constructing, maintaining, and operating bridges and other collateral facilities required on account of such crossing, not only as originally made, but all changes or alterations made thereafter on account of changes in the waterway or the character of traffic on such waterway.

"3. When a waterway is improved by widening, straightening, deepening or otherwise, or the character of traffic on the waterway is changed by improvements elsewhere, or by changes in the design of vessels using the waterway, or by changes in methods of waterway transportation, which require changes in the bridges or other collateral facilities carrying land transportation agencies over such waterway, the governmental authority in charge of and providing the funds for the waterway should bear the expense of making such changes in the bridges or other collateral facilities, and the additional expense of maintaining and operating such altered bridges or facilities over and above the expense of the maintenance and operation of the bridges and facilities as they existed before such changes were made.

"4. Any agency providing facilities for land transportation, crossing a navigable waterway, requiring, for its own purposes, changes in the bridges carrying it over the waterway, its collateral facilities, or in the waterway itself, the land transportation agency should bear the expense of making such changes, and the additional expense of maintaining and operating such altered bridges or facilities over and above the expense of the maintenance and operation of the bridges and facilities as they existed before such changes were made."

I wish to offer and move the adoption of this resolution:

"It is the sense of this Association that the principles set forth in the report of the Committee as to the allocation of the expense of the construction, maintenance and operation of bridges and other collateral facilities over navigable waterways are equitable."

The President:—This motion is also not strictly in accord with our general rules. However, the Committee wishes the expression of the convention on this subject, and the Chair will put the motion unless there is objection to it.

Mr. J. B. Jenkins (Baltimore & Ohio):—I am heartily in sympathy with the idea expressed, and I am glad the Committee used the word "should". It is a thing that ought to be done but, unfortunately, it cannot be done. No Congress can tie down any subsequent Congress as to expenditures. No Congress can make a contract by which the Government shall contribute certain amounts of money to maintenance, for example. The funds for maintenance must be appropriated by each individual Congress without respect to what any previous Congress has done.

The President:—Is there any further discussion? All those in favor of the motion will vote "aye"; contrary. It is carried.

Chairman W. C. Swartout:—That concludes the report of Committee XXV—Rivers and Harbors.

The President:—This Committee has done a vast amount of work, and they are to be complimented on their fine report. They are now excused with our thanks (Applause).

Mr. E. E. R. Tratman (Civil Engineer—by letter):—To supplement the report on protective fenders for piers and wharves, as given on page 683 of the 1934 Proceedings, it may be noted that a more elaborate system of hydraulic cushion fenders is used on the Verdon pier at the port of Bordeaux, France, which pier is used by large passenger steamers. These fenders are spaced about 100 ft. apart along the face of the pier. Each fender is about 20 ft. high and 33 ft. long, weighing 30 tons. It consists of a pair of vertical steel frames faced with horizontal timbers on the water side, and suspended from trunnion bearings just below the level of the floor or deck of the pier. Its outer face, or water side, is convex, and with the fender hanging free this face is inclined outward from the vertical, the fender being held in this position by means of counterweights on arms projecting from the rear of the fender frame. Connecting rods attached to the rear of the frame are attached also to the plungers of oil cylinders mounted below the deck and inclined slightly below the horizontal. Small pipes connect the cylinders with a larger oil main served by a pressure tank. The fender is not continuous, but a series of fenders is arranged at intervals along the face of the pier. The force or shock of a ship coming alongside is taken by the suspended fenders, which swing inwards, driving the plungers back into the cylinders and thus forcing the oil out through the small pipes and into the main. The passage of the oil through these small openings opposes or checks the movement of the fender. When the pressure against the fenders is released, as by the departure of the ship, the counterweights restore them to the normal position and the pressure in the oil tank then causes the oil to flow back into the cylinders as the plungers are withdrawn. In principle, the action is similar to that of the hydraulic buffers used in some of the large terminal stations on English railways, each buffer consisting of a pair of horizontal cylinders with piston rods ending in buffer heads which are struck by the buffers attached to the locomotives and cars of those railways.

## DISCUSSION ON IRON AND STEEL STRUCTURES

(For Report, see pp. 1011-1064)

Mr. A. R. Wilson (Pennsylvania):—The report of this Committee is found in Bulletin 364, starting on page 1011. We present herewith report covering the following subjects:

Revision of Manual, found in Appendix B; tests of steel columns and formulae for design; use of alloy steels for structural purposes; impact—railway bridges, and bearing values of small rollers, found in Appendix A.

On the other subjects in our assignment, we report progress and have asked for their reassignment.

On the four subjects in Appendix A, tests of steel columns and formulae for design, use of alloy steels for structural purposes, impact—railway bridges, and bearing values of small rollers, the reports of these four Sub-Committees are included in the Specifications for Steel Railway Bridges, Appendix B.

Appendix B, Revision of Manual, Specifications for Steel Railway Bridges, for fixed spans not exceeding 400 feet in length. This specification has been entirely rewritten and revised and is issued as First Edition—March, 1934. The first specification prepared by this Committee for steel railway bridges was in 1903. Current revisions have been made, the last revision being in 1931.

I would call your attention to several major changes in this specification over the previous specifications: The recommended live load is E-72. On the new formulae for impact, the supporting data will be presented in a coming Bulletin of the Association.

The unit stress for carbon structural steel, the basic unit stress, has been raised to 18,000 lb. per sq. in. Column formulae and materials—the materials, particularly the structural steel, are in accordance with A.S.T.M. Specifications A-7-33 Tentative. These specifications for material have been adopted after close cooperation with the corresponding committee of the American Society for Testing Materials. I have been assured that at the coming convention of that society, which will occur in June, this new standard for structural steel, which is now tentative, will be advanced to standard.

In presenting this specification it is the desire of this Committee that we receive full, written criticism on the specification, and by that means the Committee hopes that it will be materially improved from that as presented. The Committee has appointed a special committee to handle such discussions and criticisms, so that in the coming meetings of our Committee they can be properly acted upon. As we are presenting this specification as information, this concludes our report.

The President:—This specification for steel bridges is a very important piece of work. We would like to have discussion on the subject, but as the Chairman has invited written discussion, I think that is the best way to handle it. It is submitted as information, but if there is any particular point that anyone wishes to raise at this time, we will be glad to hear it. Otherwise we will receive the report as information.

Mr. S. F. Grear (Illinois Central):—This is such a change from previous specifications, especially in its basic allowable stress, it seems to me it would be a little better if that were brought out on the floor here. What brings about such a decided change? Is it permissible to ask the Committee for that information?

Chairman A. R. Wilson:—The allowable unit stress is based on the material which we have specified which, if you will notice, the elastic limit has been raised, the ultimate strength now being 60,000 to 72,000. The old specification was 55,000 to 60,000. We feel justified in using the higher unit stress.

Mr. Meyer Hirschthal (Lackawanna):—There is just one point I should like to call attention to, in addition to the question of loading that was discussed earlier between ourselves, and that is the question of the "Loads received from two tracks," provision whereby for spans less than 175 ft. two tracks are considered for impact, whereas for a span over 175 ft. one track is considered.

I imagine that it would be preferable to have some sliding percentage or factor that would be applied rather than that abrupt change from, say 175 ft., to have two tracks, and for 176 ft., to have one track applied in the impact.

I am just making that suggestion for consideration, whether it would not be possible to have some factor applied rather than an abrupt change at some point.

Chairman A. R. Wilson:—We will take Mr. Hirschthal's suggestion into consideration.

The President:—Is there any further discussion?

Mr. Theo. Doll (Santa Fe):—In connection with the question of Mr. Hirschthal, I wish to make a suggestion. I hope I am not talking out of turn when I say I happen to know that the Committee has made some very important investigations, and one of them was an investigation of the loads that should be used on multiple track bridges. There are other investigations, also, that I do not want to mention, because I prefer to leave it up to the discretion of the Committee as to how far they want to follow my suggestion; but I think it would be an excellent thing if, when this new specification is submitted for adoption or preferably before it is submitted for adoption, the Committee would publish the results of some of these investigations. Some of them are very valuable and very interesting and would be useful not only to railway Engineers but other Engineers as well. If the investigation concerning multiple track bridges was published, I have an idea that Mr. Hirschthal's question would be answered.

Chairman A. R. Wilson:—It is the Committee's intention, before asking for adoption of these specifications, to present the supporting data from which we have drawn our conclusions.

The President:—If there is no further discussion, this report will be received as information.

Chairman A. R. Wilson:—That concludes the report.

The President:—This Committee is relieved with the thanks of the Association for their very good work this year (Applause).

## DISCUSSION ON ECONOMICS OF RAILWAY LOCATION

(For Report, see pp. 671-674)

(Vice-President Robert H. Ford in the Chair.)

Mr. F. R. Layng (Bessemer & Lake Erie):—The report will be found in Bulletin 363, page 671. The only subject on which the Committee reports this year is to give a definition of "Rise-and-Fall." The report starts with several definitions that are quoted from various authorities.

A study of these definitions reveals that different values may be obtained for the amount of "Rise-and-Fall". Where the termini of the section of road for which "Rise-and-Fall" is to be determined are at the same elevation, no confusion arises in computing it, the answer being the summation of vertical rises in the profile, as it is evident that for each foot of rise there will be a corresponding foot of fall. Where there is a difference of elevation between the termini of the section of line under consideration, confusion arises in the determination of the number of feet of "Rise-and-Fall", as it is evident that there will be a difference between the sum of the vertical rises and the sum of the vertical fall by the difference in elevation between the termini.

As traffic in practically all cases moves in both directions over the same grades, it seems sufficient for all practical purposes to compute "Rise-and-Fall" for a round trip over the section under consideration. Under this method the total rises and total falls become equal, and the "Rise-and-Fall" for the line is given by one-half the sum of the vertical ascents for a round trip. While the amount of "Rise-and-Fall" obtained from the computation of same for a round trip does not exactly fit the theory under which the effect of "Rise-and-Fall" on operating expenses is treated, no great error is incurred, and as the effect of "Rise-and-Fall" on operating costs is of minor importance, the errors inherent in this method will be of little consequence.

The main effect of "Rise-and-Fall" is in fuel and time. At the present time the Committee is not prepared to offer any method of determination of the effect of "Rise-and-Fall" on these items of operating expenses or to state whether or not other items of operating expenses are affected by same, and to what extent.

It is recommended that the following definition of "Rise-and-Fall" be adopted: "Rise-and-Fall" is the sum of vertical ascents in rising from a starting point or level to a summit and returning to same point or level, inclusive of all grades on the profile between any two points or termini. It is mathematically expressed by the formula—

$$\frac{\text{Sum of ascents in one direction} + \text{Sum of descents in same direction}}{2}$$

2

I move the adoption of this definition.

Vice-President Robert H. Ford:—You have heard the report of this Committee. It is their recommendation that this be adopted for inclusion in the Manual. Are there any questions? If not, all those in favor will signify by saying "aye"; contrary-minded. It is adopted for inclusion in the Manual.

That is all the Committee have to report. They are excused with the thanks of the convention (Applause).

Mr. J. L. Campbell (Past-President—by letter):—The Committee on Economics of Railway Location presents to the 1934 convention of the American Railway Engineering Association a report upon "Rise-and-Fall" wherein it recommends a definition of "Rise-and-Fall" based upon the common interpretation that one foot of "Rise-and-Fall" consists of a rise of one foot and a fall of one foot, but wisely points out that mere summation of such rise and fall under the definition cannot be used to find cost of rise and fall. The Committee also says that it is not prepared to present a method for finding such cost.

Some reasons why the statement of the Committee is true appear in consideration of the following Fig. 1.

FIG. 1.

In Fig. 1, there are five grade lines, AF, ABF, ACF, ADF, AEF, each 20 miles long and rising 316.8 feet, the 0.3 grade line AF being assumed to be the grade of repose on which rolling resistance equals grade resistance, each being at the rate of 15.84 feet per mile, and said rolling resistance at 15.84 feet vertical per mile being constant for all grade lines. Then, in moving trains at uniform speed on the grade lines named, work done in terms of feet vertical would be as follows:

|       |       |      |        |      |        |       |        |
|-------|-------|------|--------|------|--------|-------|--------|
| On AF | ..... | East | 633.6— | West | 316.8— | Total | 950.4  |
| " ABF | ..... | "    | 633.6— | "    | 396.0— | "     | 1029.6 |
| " ACF | ..... | "    | 633.6— | "    | 475.2— | "     | 1108.8 |
| " ADF | ..... | "    | 633.6— | "    | 554.4— | "     | 1188.0 |
| " AEF | ..... | "    | 633.6— | "    | 633.6— | "     | 1267.2 |

The work done by the drivers and the brakes would be as follows:

|       |       | By Drivers |        | By Brakes |       |
|-------|-------|------------|--------|-----------|-------|
| On AF | ..... | East       | 633.6— | West      | 0.0   |
| " ABF | ..... | "          | 633.6— | "         | 79.2  |
| " ACF | ..... | "          | 633.6— | "         | 158.4 |
| " ADF | ..... | "          | 633.6— | "         | 237.6 |
| " AEF | ..... | "          | 633.6— | "         | 316.8 |

In the first tabulation above, the work east is the sum of rolling resistance and grade rise resistance, each being equal to 316.8 feet vertical. The work west is the sum of the grade fall resistance, 316.8 feet vertical, and rolling resistance in feet vertical on the level part of the grade line.

In the second tabulation, the work east by the drivers is the same as the work east in the first tabulation, also done by the drivers. The work west by the drivers overcomes only rolling resistance on the level part of the grade line. The work west by the brakes is the difference in feet vertical between the fall of the inclined part of the grade line and rolling resistance on that part. There is no brake work east.

The difference in feet vertical between the fall of a grade line and rolling resistance thereon, when the first is greater than the second, is the only part of the fall which is effective in creating cost of rise and fall. Each grade line in Fig. 1 falls 316.8 feet. On each, effective fall, overcome by the brakes, and ineffective fall, overcome by rolling resistance, are as follows:

|             | <i>Effective</i> | <i>Ineffective</i> |
|-------------|------------------|--------------------|
| On AF ..... | 0.0              | 316.8              |
| " ABF ..... | 79.2             | 237.6              |
| " ACF ..... | 158.4            | 158.4              |
| " ADF ..... | 237.6            | 79.2               |
| " AEF ..... | 316.8            | 0.0                |

Also, any rise of any profile grade against direction of train movement not in excess of allowable velocity head due to grade at the foot of such rise is ineffective.

Ineffectiveness of much of the rise and fall found on railway profiles is a reason why summation of total rise and fall computed by a composite unit composed of one foot of rise and one foot of fall is not a measure of or a basis for measuring cost of rise and fall.

Discovery or development of unit costs in items of operating expense due to rise and fall is a complex and difficult problem not yet solved. An opportunity is open to the Committee.

For fuller consideration of the problem, see the monograph by the writer in A.R.E.A. Bulletin 336, June, 1931.

## DISCUSSION ON ECONOMICS OF RAILWAY OPERATION

(For Report, see pp. 879-922)

(Vice-President Robert H. Ford in the Chair.)

Mr. J. E. Teal (Chesapeake & Ohio):—The report of Committee on Economics of Railway Operation will be found on page 879 of Bulletin 364.

Your Committee reports progress on assignments 2, 4, 7 and 8.

Under assignment (1), Revision of Manual, including revision of the method for the determination of proper allowances for maintenance of way expenses due to increased use and increased investment, your Committee presents Appendix A, which will be found on page 880.

Since the subject-matter pertaining to maintenance of way expenses now appearing in the Manual on pages 1421 to 1432 inclusive was adopted in 1925, there have been changes in maintenance of way practices which have led to the suggestion that the "use-factors," that is, per cent affected by the use, conform to current practice.

It is generally understood that these figures were based on Class I railroad operating expenses applicable to the test period, 1913, 1914 and 1915, and are subject to adjustment when applied to individual carriers. As stated in the Manual on page 1430, "these percentages may be varied to suit the circumstances of each particular problem."

After carefully considering this question during the past few years, your Committee is of the opinion that there has not been sufficient change in maintenance of way practices or sufficient further information developed to warrant any changes, especially in view of the wording of the text quoted.

However, your Committee have found that this material has been used under conditions and for purposes contrary to the original intention, which has led to erroneous deductions; and therefore recommend that the following cautionary paragraph be in-

cluded in the Manual on page 1432, immediately below the first paragraph at the top of the page:

"Care should be exercised in selecting the period to be used as the base period for comparisons. The total equivalent gross ton miles in the base period should be the normal equivalent gross ton miles, that is, the normal use for which the property is maintained. The base period should extend over a sufficient period, with normal conditions, in order that the maintenance expenditures during the period will be normal. Comparisons of one year with another cannot be made under this method, unless the equivalent gross ton miles and maintenance expenditures for the year used as the base period are the normal equivalent gross ton miles and normal expenditures for the property."

I move that this addition be adopted and printed in the Manual.

Vice-President Robert H. Ford:—Is there any question or discussion? The Chair hears none. All those in favor of its acceptance will signify by saying "aye"; contrary-minded. It is carried. The section is adopted for inclusion in the Manual.

Chairman J. E. Teal:—The report under assignment (3), methods or formulae for the solution of special problems relating to more economical and efficient railway operation, will be found as Appendix B on page 880. This report relates to the economic effect of the 131-lb. RE rail section on the cost of operation as compared with the 130-lb. RE section.

The primary interest of this Committee in rail sections is that of the effect on the cost of operation. Without intent of trespassing on the assignments of other committees, we have, in our investigations, made use of an analytical method that has previously been presented to the Association in detail and which should, therefore, require little explanation. However, this method not only includes consideration of effect on train operating costs, but also those of the correlated subjects, maintenance of track and equipment. We have, accordingly, included those structures in our study as a matter of interest. The results shown by our analysis in this particular case indicate a distinct trend of improvement in the 131-lb. RE section as noted in our conclusion. The report is submitted as information, and I so move.

I might say that Mr. C.H.R. Howe is Chairman of this Sub-Committee and will be glad to answer any questions that may arise.

Vice-President Robert H. Ford:—Are there any questions?

Chairman J. E. Teal:—The report under assignment (5), methods for determining most economical train length, considering all factors entering into transportation costs, etc., appears on page 890. It is in two parts. The first part deals with locomotive capacities, and the second part deals with road and yard switching performances. Both have an important bearing upon the factors which affect transportation costs.

A theory in regard to steam locomotive capacities was developed last year for the purpose of determining the weight of train and the speed which would give the maximum gross ton miles per train hour. Other applications have been found where the method can be used as a short cut in preliminary estimates of locomotive performances, which is the reason for supplementing last year's report.

The text describes some of these applications, and others will suggest themselves when one becomes familiar with the uses of the chart on page 891 and the tables on pages 895 to 903.

The chart indicates the range covered by various classes of steam locomotives and offers a convenient way to estimate the horsepower capacity for the weight of the engine and the weight on drivers for the different types of locomotives.

Having determined the horsepower capacity of a locomotive, the tractive effort at

various speeds can be rapidly calculated by following the form on page 893 which is shorter than the method usually followed.

Part II of the report, beginning on page 904, is a preliminary introduction of two more factors which enter into the problem, for the purpose of attracting attention to the relation of yard switching performances and road performances. Analysis of these relations will be discussed in the Committee report next year.

The report is offered as information, and Mr. L. S. Rose is Chairman of the Sub-Committee. He and other members will be glad to answer any questions that may arise at this time.

Vice-President Robert H. Ford:—Are there any questions? The Chair hears none.

Chairman J. E. Teal:—The report under assignment (6), effect of volume of traffic on railway operating expenses, will be found as Appendix D on page 910. This is a large subject and very apropos. Your Committee has been giving considerable thought to this subject since its assignment in 1931 and now offers the first progress report. Mr. S. W. Fairweather, Chairman of the Sub-Committee, is unable to be present. However, if there are any questions, other members may be able to answer them. The report is offered as information.

Vice-President Robert H. Ford:—Are there any questions? The Chair hears none.

Chairman J. E. Teal:—That concludes our report. In connection with the last one I find a few typographical errors which will be straightened out with the Secretary.

Vice-President Robert H. Ford:—Gentlemen, you have heard the report of the Committee on Economics of Railway Operation. Are there any questions?

(NOTE.—Corrections referred to above are as follows: Page 913 middle of page: axis is  $\bar{y} - y_a$  should read axis is  $\bar{y} - \bar{y}_a$ .

Page 916 first line following table:  $z = .879 + 5.545$  should read  $z = .879_x + 5.545$ .

Also fourth line first paragraph:  $z = .879 + 5.545$  should read  $z = .879_x + 5.545$ .)

Mr. Edwin F. Wendt (Consulting Engineer):—I do not have any question to ask but I rise to express my appreciation of the work of this Committee, not only during the past year but previous years. It seems to me that it would be difficult to assemble another group of men in this country who are so well informed on the subject of economics of railway operation.

The Committee has considered an especially difficult question during the past four years, during which time traffic has been on a rapid decline. You may remember that during the great panic of 1893, which lasted for six or seven years, the railroads lost 12 per cent of their gross earnings. There has been no other panic in the history of our American railroads, previous to the present time, when the railroads suffered so greatly.

When the depression of 1893 was concluded, the American Railway Engineering Association was formed. I am under the impression that it was that great period of depression which caused the founders of this organization to come together and to begin what has been the greatest work done in railway engineering during the past century.

Now, I should like the privilege of stating for the record a few facts which I think are most significant, particularly at this time when the severity of the depression (1929-1933) has been passed.

The Interstate Commerce Commission recently submitted to Congress its forty-seventh annual report in which it made some most significant statements, for example:

Freight revenue of Class I steam railways compared with the average revenue in the years 1927, 1928 and 1929, taken as 100 per cent, declined from 100 in the base period to 44.1 in March, 1933. There was a drop of 55.9 per cent compared with only 12 per cent in the great panic of 1893. While traffic in March, 1933, was the low point

in the past depression, it is a fact that the index of traffic stood at 45.6 in August, 1932. In other words, this low period of traffic extended over a period of almost nine months.

During the same period the average number of employees of Class I steam railways compared with the average number in 1927, 1928 and 1929, taken as 100 per cent, declined from 100 in the base period to 54.7 in May, 1933. This was the low point during the depression. You will notice that the decline in the number of employees was almost 10 per cent less than the decline in gross revenue. The index for employment in August, 1932, was 56.5, which was the lowest in that year.

We all know there has been fierce competition during the period of the depression, and I think it is significant that the Commission made a certain statement regarding the various forms of transportation. They observed:

"It is obviously not desirable to restrict this competition in so far as it is conducted on a fair basis. However, before such a condition of fair competition can be said to exist, it will be necessary that the various transport agencies pay the same rates for comparable skill, render reliable service on a non-discriminatory basis, and bear an equal tax burden."

The Commission also stated:

"As disclosed by the record" (general rate level investigation 1933) "the railroads have suffered from the depression as much as, if not more than, industry in general, the year 1932 and the first quarter of 1933 having been their worst periods in many decades."

The Commission also stated:

"A large part of the burden of maintaining an adequate transportation system was formerly borne by the high-grade commodities, but today much of this traffic either is lost to motor or water carriers or is handled at rail rates which produce little or no profit."

One thing more. During the past depression there were thousands of Engineers out of work. There are in this country 200,000 Engineers of all classifications. While there is no record of the number of unemployed, it certainly ran from 50,000 to 100,000. An Engineer told me yesterday that he had been in charge of certain engineering parties working in the Central West and that he was losing men. They were resigning to enter private industry. That is one of the best signs of the times.

Another good sign is the increase in activity of business, particularly railroad business, in the Pittsburgh territory. You know that Pittsburgh is one of the best barometers in the whole United States. The increase in business of the Pittsburgh territory in the month of February, 1933, over a similar period in 1932 was 35.8 per cent, and the increase in business in February, 1934, over January, 1934, was 10.4 per cent. These figures were compiled by the Bureau of Business Research, University of Pittsburgh, and are based upon production, iron and steel, electric power, coal, rail shipments and trade. They are reliable because the University receives its information from shippers and business people.

I make this statement because I think that we are now facing a much brighter future in which the railroads will regain a large part of the business which was lost, and as railroads prosper there will be much more work for the Engineer. It seems to me that that is something for which we can congratulate ourselves, because increased employment is much to be desired in behalf of the thousands of Engineers who have been out of employment during the depression.

Vice-President Robert H. Ford:—Mr. Teal, you and your Committee are excused. Gentlemen, that is among the best reports of the convention (Applause).

## DISCUSSION ON ECONOMICS OF RAILWAY LABOR

(For Report, see pp. 645-662)

(Vice-President Robert H. Ford in the Chair.)

Mr. Lem Adams (Oxweld Railroad Service Company):—The report of Committee XXII—Economics of Railway Labor, will be found in Bulletin 362, page 645. While we have completed but three of the subjects assigned to us this year, the Sub-Committees have done a large amount of work on their subjects.

On Subject (1) the Committee have reviewed the Manual but do not find anything to report for change at this time.

Subject (2), analysis of operations of railways that have made marked progress in the reduction of labor required in maintenance of way work. We are not going to make a formal report on this subject this year as Mr. Parant, our Sub-Committee Chairman, is not here. The Committee went over the Lehigh Valley with Mr. G. A. Phillips, Chief Engineer, and looked over the railroad that we had made some very intensive studies of in our report a few years ago. We found conditions there very good. However, we do not know how to approach this subject at this time, as so many varying conditions have existed since we started this report. We wish only to report progress on that subject.

Subject (3), effects of recent developments in maintenance of way practices on gang organization. Mr. Schwinn, Chairman of this Sub-Committee, went into this subject very thoroughly and presented a report to the Committee. The report was very interesting and very thoroughly gotten up, but we have found so many variables that have come into track maintenance that we decided it was best not to present the report, not even as a progress report. We are asking that this subject be discontinued for a time, until we feel more certain of our grounds and whether or not the economies that we have made in force reduction during the past several years are economies that will be perpetuated.

Subject (4), methods of reducing work-train service and economies in maintenance expenses effected thereby. Mr. O'Rourke is Chairman of the Sub-Committee, and I will ask him to please present a brief report.

Mr. G. M. O'Rourke (Illinois Central):—The report is given in Appendix B, pages 646 to 652, inclusive, Bulletin 362. Expenditures made for work-train service on Class I railroads in the United States during the seventeen years ending 1932 are shown on page 646. On the opposite page the principal means of reducing work-train service are listed. On the following pages your Committee has gone into the details of many of the methods adopted to reduce this expense, finally reaching the conclusions presented on page 652. Those conclusions are:

"1. That maintenance of way operations should be carefully planned to reduce the number of work trains required.

"(a) By so programming the work as to permit it to be done in consecutive order and eliminate duplicate movements.

"(b) By utilizing spare time of light extra and local trains.

"(c) By having a thorough understanding by all concerned in the transportation and maintenance departments regarding work to be done and time required to do it.

"(d) By insuring that locomotives assigned have sufficient power to handle the work.

"(e) By loading materials in suitable cars.

"(f) By selection of the proper type of crane for unloading and loading rail and having a properly organized gang experienced in the kind of work being done.

- "(g) By lining up work to be done in consecutive order to avoid backup movements and having sufficient work for a full day's work-train service.
- "(h) By the extended use of motor cars to handle men and material.
- "(i) By the use of other self-propelled equipment wherever suitable.
- "(j) By further development and use of off-track equipment."

Your Committee recommends this report be accepted as information and the subject discontinued.

Vice-President Robert H. Ford:—The Committee recommends that this be received as information. Is there any objection? It will be so received.

Chairman Lem Adams:—Subject (5), programming of bridge and building work. Inasmuch as the subject-matter which the Sub-Committee Chairman will report is Manual material, we would appreciate your giving this very careful consideration. Mr. Botts will please present the report.

Mr. A. E. Botts (Chesapeake and Ohio):—The report of Sub-Committee (5), programming of bridge and building work, appears in Bulletin 362, pages 652 to 656, inclusive.

The object of this report is to provide a simple method whereby material and labor requirements for bridge and building maintenance can be accurately forecasted and the execution of the work programmed. This is accomplished by the use of three forms, namely:

Form 1, found on page 654, is used for recording material and labor required for each individual bridge or structure and is to be filled out at the time of field inspection. This information is furnished the general office and is the basis for the preparation of the program. Each project listed in the field is classified as to whether it is improvements to existing facilities or straight maintenance of a major or minor character by the use of letters "A", "B", and "C", as described in the report.

The actual programming of the work is accomplished by the use of Form 2, found on page 656. On this form are included estimated costs, accounting reference, and a careful scheduling of the work by months. This form may also be used as a progress report and a means of assembling final costs.

Form 3, annual bridge and structure force program, found on page 656, is for use by division officers for scheduling program by forces.

Your Committee recommends this report be adopted for inclusion in the Manual as recommended practice, and I so move.

Vice-President Robert H. Ford:—It is moved and seconded that the report as read be adopted and included in the Manual. Are you ready for the question? All those in favor will signify by saying "aye"; contrary-minded "no." It is a vote, and the report will be included in the Manual.

Chairman Lem Adams:—Subject (6), revised plans for outfit cars for maintenance of way department employees. This is a subject that has been before us for a number of years. While some of the plans which the Sub-Committee Chairman will present to you may be considered elaborate, there are a number of such outfits so equipped and in service on several railroads throughout the country today, and the Committee feels that these plans should be given your careful consideration. Mr. Magee will please present the report.

Mr. G. M. Magee (Kansas City Southern):—The report of the Sub-Committee assigned to prepare revised plans for outfit cars for maintenance of way department employees appears on pages 657 to 661 of Bulletin 362 as Appendix D.

Study was made of various types of outfit cars in use on different roads. From this study two series of plans were presented. One series provides for construction of outfit cars from retired passenger equipment, and the other from freight equipment.

In preparing these plans we have attempted to show a typical layout to accommodate workmen who are accustomed to a higher standard of living than is provided by early-day outfit cars. The individual roads may pattern in accordance with these general plans, with modification to suit the standard of living desired. Ten points of consideration are given, which should be borne in mind in making these modifications.

Your Committee recommends that this report be accepted as information, and the ten points of consideration on pages 657 and 658, together with the two series of outfit car plans be included in the Manual as recommended practice.

Mr. W. A. Radspinner (Chesapeake & Ohio):—These cars as they are shown only present a floor plan, but when they are put out on the road they are heated by ordinary stoves, or whatever happens to be standard on that railroad. The same kind of a smokejack would not be used on a camp car or ordinary box type, as on the passenger coach. When they get these cars out in cold weather they force the stoves, so that the first thing you know the whole thing is on fire.

I think that one of the points the Committee should consider is protection against fires of that kind. The range should be properly located and protected, and the smokejacks in these cars should meet with the requirements of the Fire Protection Association.

Vice-President Robert H. Ford:—Is there any other question or further discussion? If not, the motion is on its inclusion in the Manual.

All those in favor will signify by saying "aye"; contrary "no." It is a vote, and it will be included in the Manual.

Chairman Lem Adams:—There are two other subjects assigned to this Committee: (7) economics of methods of weed killing. Mr. Harsh is Chairman of this Sub-Committee. We have not done anything more on this subject other than to continue the study this year, but we hope in our next year's report to be able to give a final report on the subject; (8) gang organization and methods of performing maintenance of way work, including revision of time studies now in the Manual. Mr. Howe, who is Chairman of the Sub-Committee, is absent. However, he advises that very little progress has been made on the report this year, and we wish to continue the subject for further study.

That completes the report of the Committee.

Vice-President Robert H. Ford:—Mr. Adams, the convention congratulates you and your Committee on the excellent and painstaking work which is evident by this report. You and your Committee are excused with the thanks of the Association (Applause).

## DISCUSSION ON STANDARDIZATION

(For Report, see pp. 1065-1077)

Mr. J. C. Irwin (Boston & Albany):—The report of this Committee is in Bulletin 364, page 1065. This Committee has nothing to present which has to be acted on by the convention, but it presents in concise form progress in standardization in matters mostly beyond the action of this Association.

Its first assignment is encourage the use of A.R.E.A. recommended practices and consider subjects for recommendation to the Board of Direction for sponsoring as projects for national standardization.

This Committee keeps in contact with the other standardization associations and carries such projects as seem to be suitable for national standardization beyond the field of the American Railway Engineering Association.

During the year the most important contact we have had was with the new organization of the Federal Coordinator of Transportation, Mr. Eastman, through his section of Purchases and Stores. On account of this Committee representing all committees, being composed of the Chairmen of all committees, the organization of the Federal Coordinator got in touch with this Committee very early, with the idea of finding out just what matters were in progress which might be shaped up to national standardization.

This contact with the Federal Coordinator of Transportation's staff, through Mr. Lockwood, Director of Purchases, and his assistants, Mr. Brown and Mr. Cooper, led to the general meeting in Chicago this fall, which was a combined meeting of this Committee with the General Committee of the Engineering Division and several of the Chairmen and Secretaries of other Divisions of the American Railway Association.

This meeting was arranged for the special purpose of giving Mr. Lockwood the opportunity of outlining to the A.R.E.A. organization the policies of the Federal Coordinator with reference to the use of recommended practices and, as far as possible, national standards.

This meeting in Chicago was really quite historic. President Wiltsee acted as Chairman of that joint portion which involved both the General Committee and the Committee on Standardization. It brought many matters into prominence, so that the Federal Coordinator's staff could see just where they stood and how to proceed with reference to A.R.E.A. practices.

Those things have been explained rather specifically in the reports of some of the other committees, notably the Committee on Rail and the Committee on Track. This is just a beginning and probably it is the greatest recognition that this Committee has had its part in extending the use of the A.R.E.A. recommended practices.

In regard to extending this use, the Committee again urges that the members of the Association try out the recommended practices as far as possible, if they are not already using them, and where they find any cases that do not fit their conditions, notify the Chairman of the Committee so that the matters can be taken up again and studied further, with the idea of eventually reaching uniform practices so far as possible.

Another assignment of this Committee is to maintain contact with standardization bodies and keep the Association informed on important matters developed by such contact. The report of this Committee consists of only eight pages, and those who have not read it I think will find it worth while to read it and find in condensed form the progress that has been made during the year on standardization matters.

The question of standardization of creosote has advanced today by approval of the A.R.E.A. Undoubtedly the joint action of the A.R.E.A., A.S.T.M., and A.W.P.A. will lead to a national standard on creosote.

The other subjects mentioned on page 1067 are under way, with a view to carrying them through to national standardization. I shall not take the time to go into them in detail, unless there is some question to be asked in regard to them.

New subjects have been presented at the meeting of the Standardization Committee, with a view to lining them up for action through the American Standards Association.

On page 1079 is a statement prepared by the Joint Committee on Grade Crossing Protection through Mr. Frank Ringer, its Chairman, with a view to presenting to the Association the status of progress in uniform grade crossing protection. On account of the short time we have, I shall not read these things in detail.

Page 1069 refers to our connection with the American Standards Association and its relation with the National Bureau of Standards. Both the American Railway Association and the National Bureau of Standards are member bodies of the American Standards Association, and they work together in that organization.

Last year Director Roper undertook to economize in the National Bureau of Standards by having the American Standards Association take over some of the simplified practice and standardization work that had been done previously by the Bureau of Standards, but no complete combination has yet been effected, although the tendency has been to throw more of the work over to the American Standards Association. The statement in regard to that situation is found on pages 1069, 1070 and 1071.

We incorporate a statement in regard to the status of standardization through the Canadian Engineering Standards Association, in which we have a large interest through our Canadian members. You will find that on pages 1071 and 1072. This statement was prepared by Mr. B. Stuart McKenzie as Secretary of the C.E.S.A. and covers Civil Engineering and Construction, Mechanical Engineering and Electrical Work.

This Committee has been making contact with the various standardizing bodies by meeting jointly with them and getting them to explain their methods, and letting them hear from us in regard to our methods and progress on standardization. As we reported before, in 1931 we met with the Bureau of Standards in Washington; in 1932 we met with the American Standards Association in New York, and this past year we had hoped to meet with the Canadian Engineering Standards Association, but the conditions in the United States prevented that at that particular time and made it advisable for us to meet with the representatives of the Federal Coordinator. We still have in mind our direct contact with the C.E.S.A. and are hoping to have a meeting there this spring which will enable us to form closer cooperation with that body than we have had heretofore.

On page 1073 you will find a list of the standards approved during the year by the American Standards Association, in which we have had a part, and a very interesting table which is now complete, on pages 1075 to 1077, showing the representatives of all Divisions of the American Railway Association that are taking an active part in the work of the sectional committees of the American Standards Association to produce national standards which are issued under the name of American Standards.

That completes the report of the Committee.

The President:—This Committee has been doing a lot of valuable work for the Association. They will now be excused with our thanks (Applause).

# INDEX

---

## A

- Accounting, statistical requirements, 614
- Address, President's, 13
- Dean A. A. Potter, 53
- Agreement forms:
  - conveyance of title granting the right to construct and maintain buildings over railway property, 320
  - pipe line crossings under railway tracks, 325
  - purchase of electrical energy in large volume, 310
  - use of railway property by pipe lines paralleling railway, with special reference to pipe lines carrying high pressure inflammable oils and gas, 325
  - with public authorities for highway grade crossing elimination or separation, 327
- Amendment to Constitution, 22
- American Standards Association, 1069
- standards approved by, 1073
- technical projects on which the railway associations are cooperating, 1075
- Armstrong, John E.:
  - election of as President, 48
  - installation of as President, 49
- Automatic train control, developments of, 333

## B

- Ballast, report, 663
- comparative cost of maintaining track on various kinds, 667
- proper depth and kind of sub-ballast, 668, 1112
- specifications for prepared gravel, 664
- questionnaire on cementing value of ballast in connection with purchasing, 666
- stone, 664
- tabulation of results and tests, 666
- Bibliography:
  - records and accounts, 581
  - yards and terminals, 463
- Bridge inspection report forms, 610
- Bridges:
  - methods of strengthening existing, 1005

## Bridges—Continued

- overhead wooden or combination wooden and steel highway, 999
- rules for maintenance of, 522
- specifications for steel railway, 1013
- Buildings, report, 529
- causes of dust explosions in grain elevators and methods of obviating the hazard, 554
- relative merits of wood and fireproof roof structures, including wood, hollow tile fire-proofing, concrete and cement tile, etc., 552
- remodeling freight houses for accommodation of truck door-to-door delivery of freight, 551
- revised specifications for built-up roofing, 530
- specifications for railway buildings, 540
  - built-up roofing, 545, 546
  - genuine wrought iron chimneys, 543
  - metal screens, 549
  - steel chimneys—welded, 540
  - wood screens, 547
- Business session, 13

- Economics of Railway Labor, report, 645
- analysis of operations of railways that have made marked progress in the reduction of labor required in maintenance of way work, 646
- gang organization and methods of performing maintenance of way work, 662
- programming of bridge and building work, 652
- methods of reducing work-train service and economies in maintenance expenses effected thereby, 646
- revised plans for outfit cars for maintenance of way department employees, 657
- Economics of Railway Location, report, 671
- definition of "rise-and-fall," 671
- Economics of Railway Operation, report, 879
- economic effect of 131-lb. RE rail section on the cost of operation as compared with 130-lb. RE section, 880
- effect of volume of traffic on railway operating expenses, 910
- methods for determining most economical train length, considering all factors entering into transportation costs, 890
- revision of the method for the determination of proper allowances for maintenance of way expenses due to increased use and increased investment, 880
- Electricity, report, 343
- summary of reports of Electrical Section, ARA, 343
- Expansion joints, design of, 986

## F

- Financial statement, 32
- Fire prevention rules, 527
- Foundations, 1183

## G

- General balance sheet, 32
- Gibboney, James Haller, A Memoir, 622
- Grade Crossings, report, 561
- merits and economy of the "stop-and-go" type of signal with red and green illuminated aspects, 575
- proper vertical curves on highways for grade separation projects, 573
- relative economy of different types of highway grade crossings, 568
- standard specifications for street crossings over railway tracks, both steam and electric, 562
- Grades for ditches, 1105
- Grain elevator storage yards and plant tracks, 434
- Gravel ballast, specifications, 664

## H

- Honorary membership, 15
- Hump yards, 441, 1092

## I

- Interstate Commerce Commission:
  - developments under Order No. 15100, 618
- Iron and Steel Structures, report, 1011
- specifications for steel railway bridges for fixed spans not exceeding 400 feet in length, 1013

## J

- Joint facility records, 603

## M

- Maintenance of Way Work Equipment, report, 473
- adaptability of air and electric driven tools in maintenance of way work, 475
- hazards of spray painting, 513
- organization for use and maintenance of ballast cleaning machines, and conditions under which each particular type may be used, 516
- standardization of parts and accessories for railway maintenance motor cars, 475
- track welding equipment (a) oxy-acetylene, (b) electric arc, 505
- types of snow-melting devices as an aid in facilitating train operation and reducing maintenance cost, 482
- use and adaptability of track type tractors in maintenance of way work, 485

# Maintenance of Way Work Equipment, report—Continued

- use and maintenance of paint spraying equipment, 510
- use of weed destroying equipment, 498

# Masonry, report, 957

- design of expansion joints, 986
- general specifications for foundations of railway structures, 976
- pneumatically projected concrete, 984
- tentative specifications for shotcrete, 984
- reinforced concrete trestle design, 958
- specifications and principles of design of plain and reinforced concrete, 958
- Tebbetts, George E., A Memoir, 957
- tentative specifications for lining railway tunnels with concrete, 979

# Materials, methods of protection of treated in the field, 765

- cleaning, 640, 1169
- corrosion-resisting, 1175

# Membership:

- deceased members, 30
